

Europrevent Stockholm- National Coordinators Meeting

7 May 2009

SCORE and HeartScore- an update

**With thanks to Marie-Therese Cooney,
Alexandra Dudina and Sophie Squarta**

**Ian Graham
Trinity College and the Adelaide and
Meath Hospital, Dublin**

Guidelines & Estimating vascular risk Outline

- **The Fourth Joint Task Force on Prevention**
- **The concept of total risk**
- **SCORE and other risk estimation systems**
- **New initiatives:-**
 1. **Risk in the young**
 2. **Total events**
 3. **BMI and HDL- important differences**
 4. **Simplifying risk estimation**
 5. **Heart rate**
 6. **Risk in the elderly**
 7. **Addition of newer risk factors**
 8. **HeartScore and the future**
- **Conclusions**

European guidelines on cardiovascular disease prevention in clinical practice: full text

Fourth Joint Task Force of the European Society of Cardiology and other Societies on Cardiovascular Disease Prevention in Clinical Practice

(Constituted by representatives of nine societies and by invited experts)

**European Journal of Cardiovascular Prevention and Rehabilitation 2007,
14(suppl2):S1-S113**

New Version
2007

EUROPEAN GUIDELINES ON CVD PREVENTION

Committee for Practice Guidelines
To improve the quality of clinical practice and patient care in Europe

CVD FULL TEXT AND EXECUTIVE SUMMARY

FOURTH JOINT TASK FORCE OF THE EUROPEAN SOCIETY OF
CARDIOLOGY AND OTHER SOCIETIES ON CARDIOVASCULAR
DISEASE PREVENTION IN CLINICAL PRACTICE

EASD
European Association
for the Study of Diabetes

www.escardio.org

4th Joint task Force on the prevention of CVD in clinical practice

Why stress assessment of total CVD risk ?

- **Multiple risk factors usually contribute to the atherosclerosis that causes CVD**
- **These risk factors interact, sometimes multiplicatively**
- **Thus the aim should be to reduce total risk; if a target cannot be reached with one risk factor, total risk can still be reduced by trying harder with others.**

How do I assess CVD risk quickly and easily?

- Those with-
 - ~known CVD
 - ~type 2 diabetes or type 1 diabetes with microalbuminuria,
 - ~ very high levels of individual risk factors

are already at **INCREASED CVD RISK** and need management of all risk factors

For all other people, the **SCORE risk charts** can be used to estimate total risk—this is critically important because many people have mildly raised levels of several risk factors that, in combination, can result in unexpectedly high levels of total CVD risk

Risk assessment- Options

- **Clinical judgement- very efficient, not always reliable**
- **FRAMINGHAM** (Previous European and current UK guidelines)- small data set (c 5K, now 8K) from one US town, but meticulous long-term follow-up.

THANK YOU!

- **ASSIGN**- Scottish data, good assessment of impact of social deprivation
- **Q RISK**- Large UK data set, not random sample with much missing data
- **PROCAM**- Moderate size, single city
- **SCORE** (Systematic Coronary Risk Evaluation)- Large (205K), representative (10 population samples) but rather few variables and uses total CVD mortality as the end point

The SCORE database

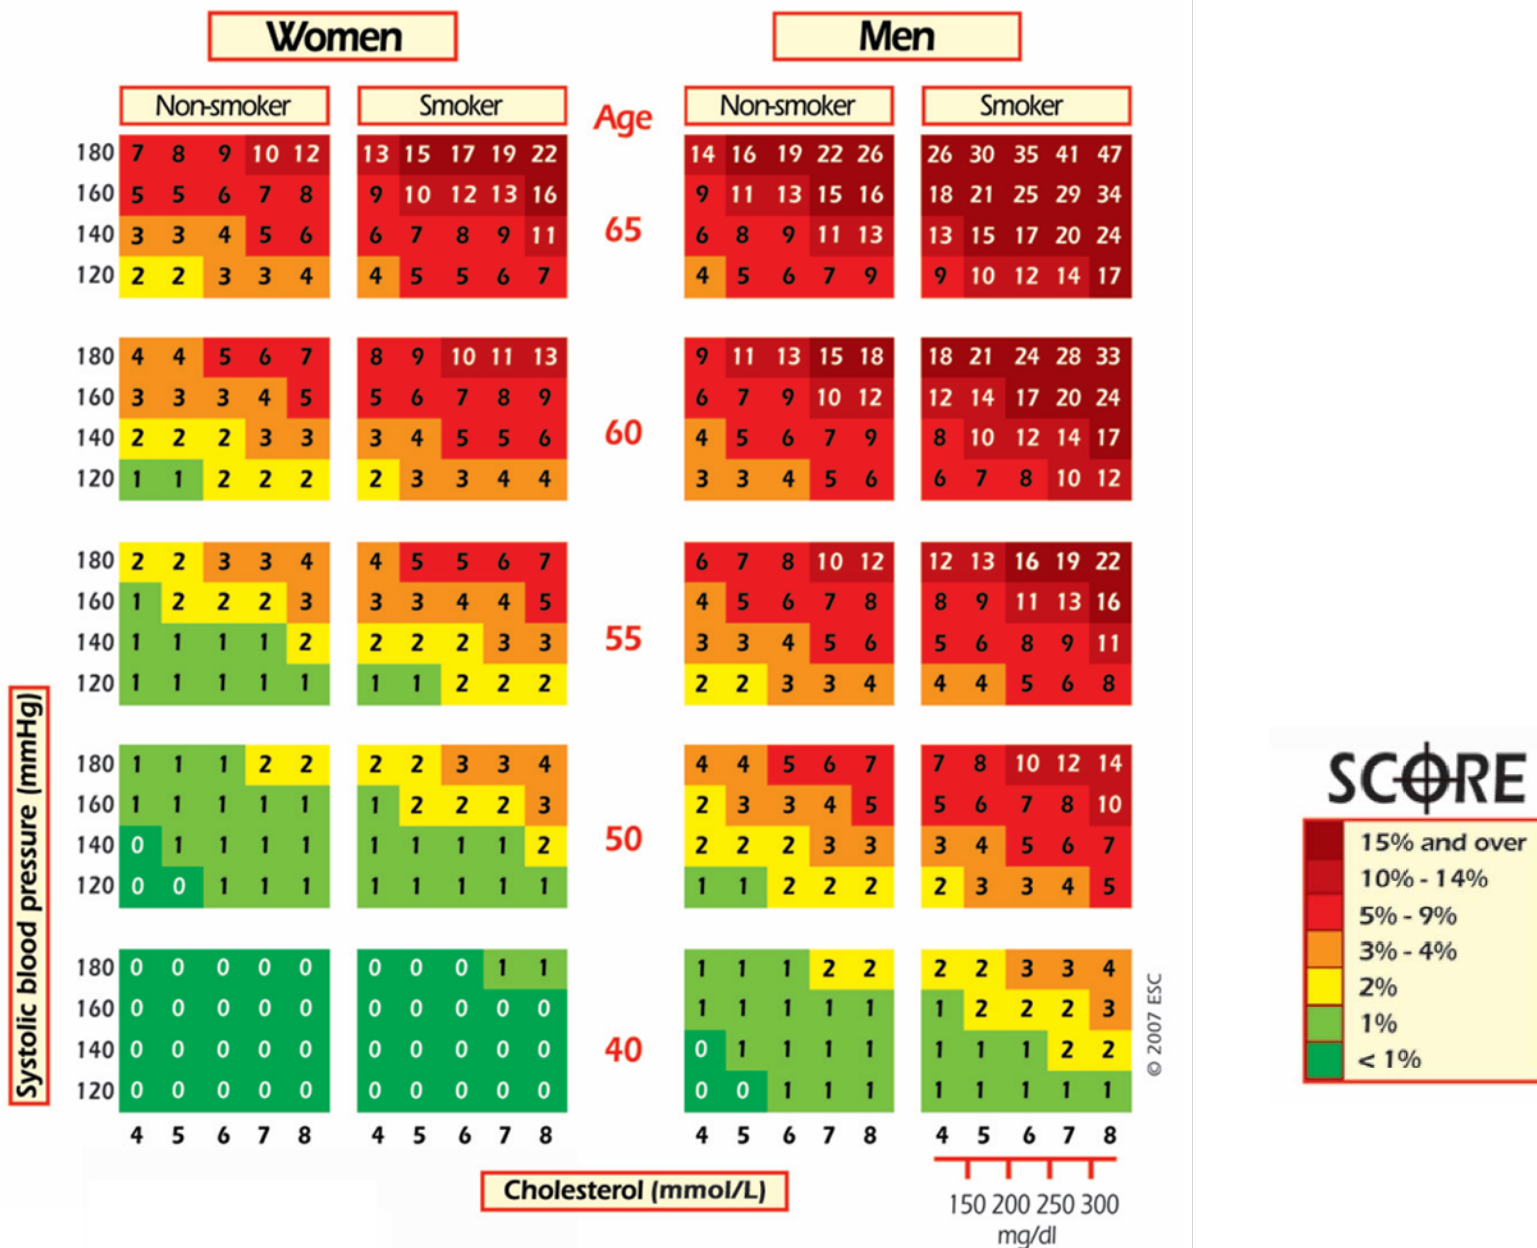

12 European cohort studies

- Some with multiple component cohorts**
- Mainly population studies**

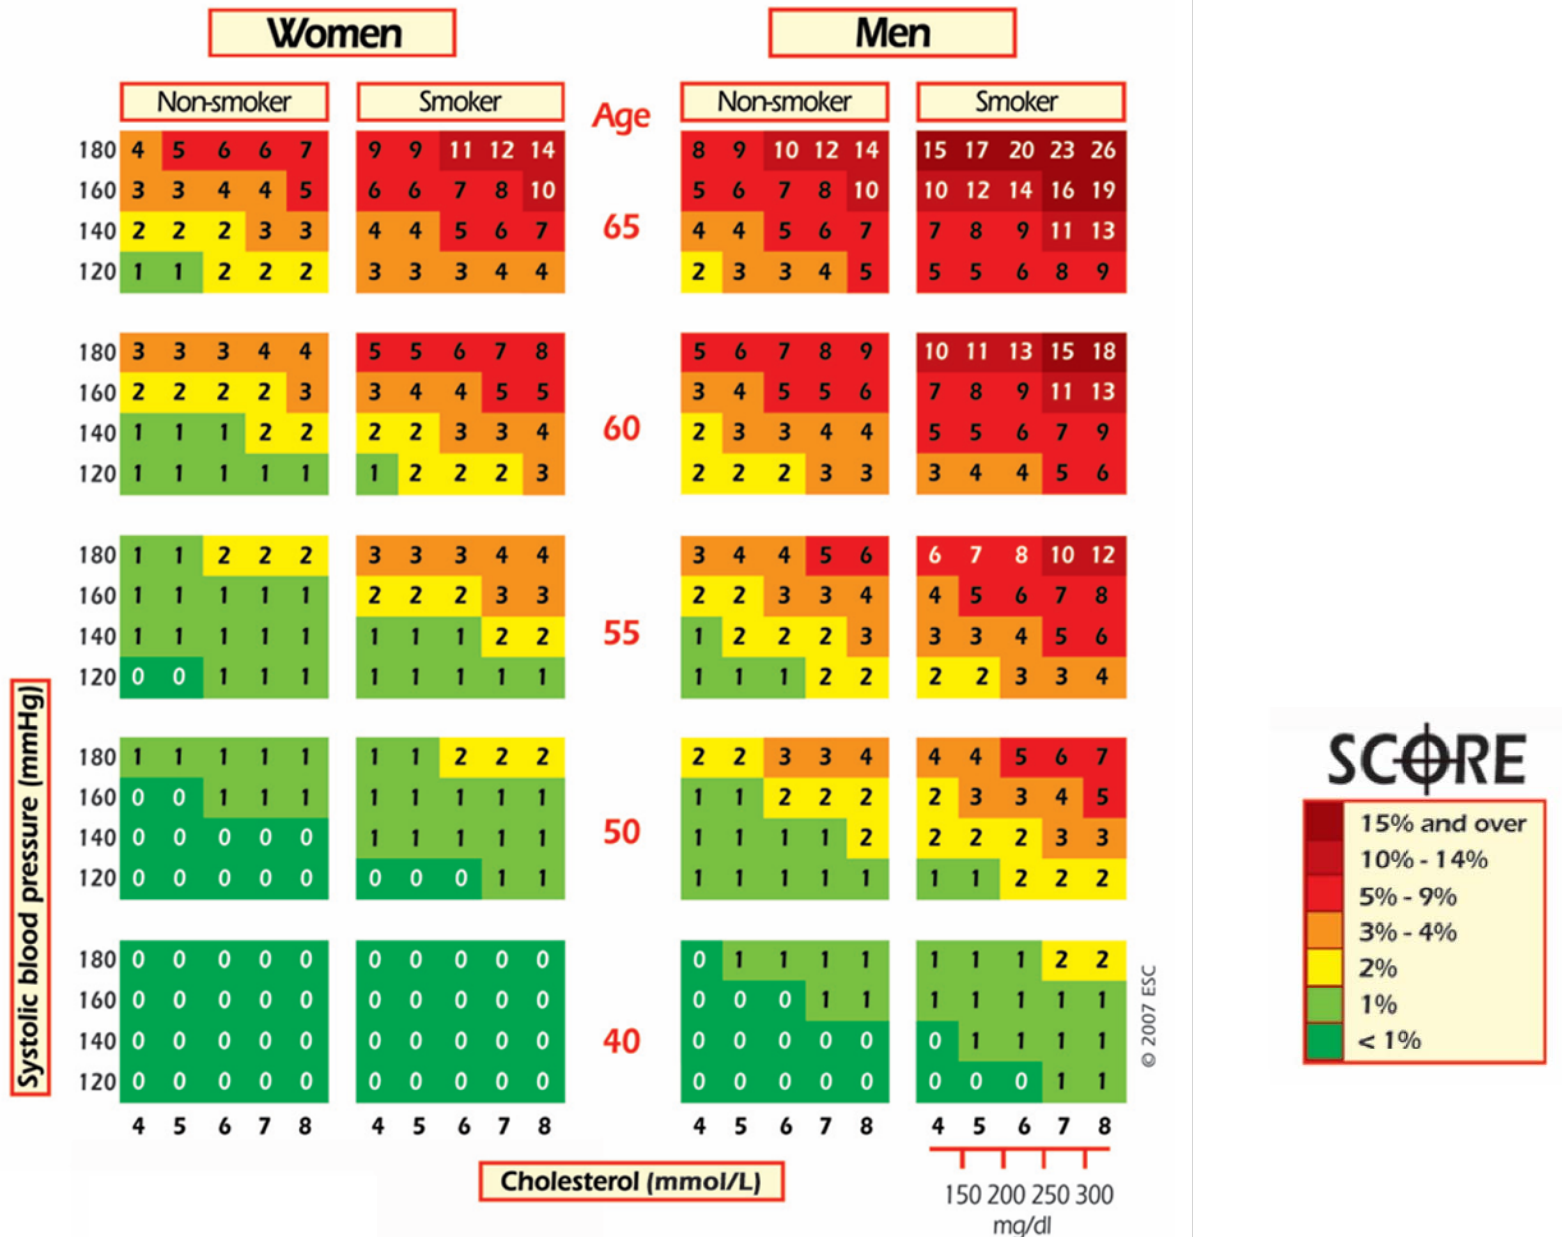

In round figures:

- 205,000 persons**
- 3 million person-years of observation**
- Over 7,000 fatal cardiovascular events**

10 year risk of fatal CVD in high risk regions

10 year risk of fatal CVD in low risk regions

SCORE summary: advantages

- Very large data set- representative
- Derived & tested on European data
- Hard, reproducible end points
- CHD & stroke risk can be derived separately
- High & low risk charts improve applicability
- Designed to evolve- new cohorts can be accommodated
- Underlying formulae can be adjusted with local mortality data- re-calibration
- Easy to develop electronic, interactive version

SCORE summary: problems

- Too simple- HDL is included as ratio, but what about obesity, exercise, family history, insulin resistance, diabetes, multiple newer risk factors? How much does it matter?
- Old cohorts- secular changes in mortality, natural history, diagnostic tests, ascertainment rates, treatments. How much does it matter?
- What about morbidity/total events?

SCORE & HeartScore- update & new initiatives

1.Risk in the young-

The problem:

A low absolute risk may conceal a very high relative or lifetime risk

Relative Risk

Women

	Non-smoker					Smoker					Age
180	7	8	9	11	14	12	15	17	21	26	65
160	5	6	7	8	10	9	10	12	15	19	
140	3	4	5	6	7	6	7	9	11	13	
120	2	3	3	4	5	4	5	6	8	10	

180	4	4	5	6	8	7	8	10
160	3	3	4	5	6	5	6	7
140	2	2	3	3	4	3	4	5
120	1	2	2	2	3	2	3	3
	3	4	5	6	7	3	4	5

Relative Risk
per 60 mm SBP
plus smoking
 $RR = 10 / 2 = 5$

Relative Risk Chart

This chart may be used to show younger people at low absolute risk that, relative to others in their age group, their risk may be many times higher than necessary. This may help to motivate decisions about avoidance of smoking, healthy nutrition and exercise, as well as flagging those who may become candidates for medication

Risk in the young

- Is the relative risk chart sufficient?
Consider-
- Attributable risk
- Years of life lost or gained
- Risk age
- Risk advancement periods
- Of these, we suggest that **risk age** is the easiest to understand

Risk Age

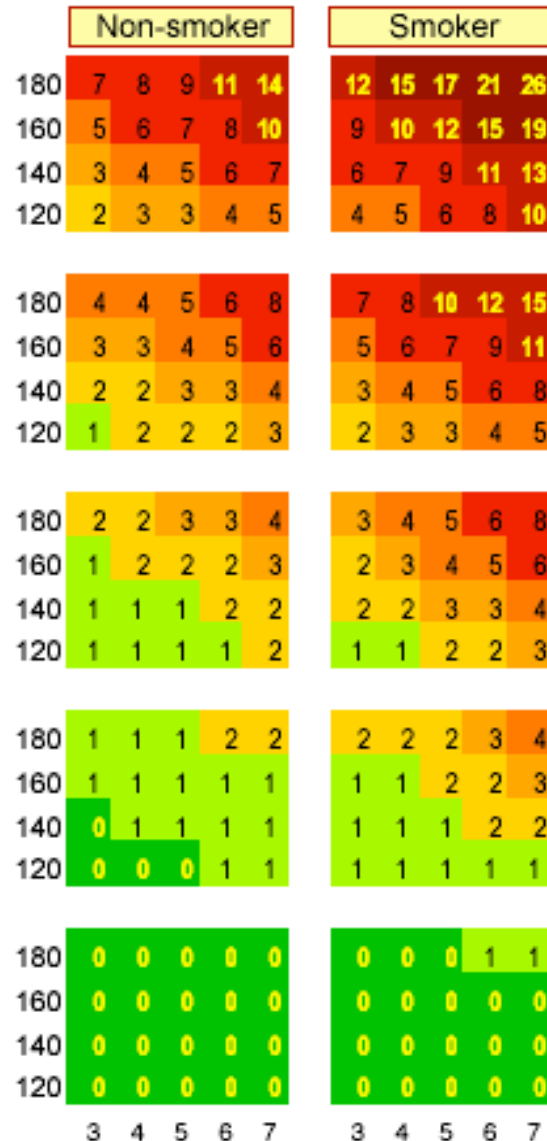

Definition:

„The age of a person with a given burden of risk factors compared with the age of a person with the same risk but who has fewer risk factors.“

Synonyms:

Heart age, cardiovascular age

Women

Men

A 40 year old man who smokes and has a high BP and cholesterol may have a “risk age” of 65 years

SCORE

10-year risk of fatal CVD in populations at high CVD risk

Total cholesterol:HDL
Cholesterol ratio

SCORE & HeartScore- update & new initiatives

2. Total events-

The problems:

Determined by multiple variables that are not stable over time, and by duration of follow up

MORBIDITY AND TOTAL EVENTS

Catherine McGorrian

[We are sorry that we have made such a meal out of this]

The prediction of total CVD events.

What do you think would be the multiplier to convert mortality to total events?

(A) 2x?

(B) 4x?

(C) 5x?

(D) 10x?

(E) 15x?

(F) None of the above?

The prediction of CVD morbidity

- Everybody wants charts for morbidity/total events
- 20% risk of a CHD event (old Framingham chart) = 5% risk of CVD death (SCORE)
- A high risk of death indicates a high risk of a non-fatal event
- **PROBLEMS**: Changes in definitions of events & diagnostic criteria, therapy, risk factors, natural history, ascertainment of events. Hard to re-calibrate. ALSO-dependent on duration of FU
- **SOLUTION??** Finnrisk-Monica collaboration to derive total-event chart- **SCOREplus**

Which lucky person gets into SCORE+ but not SCORE?

A-----F

B-----NF-----F

C---NF---NF---NF---NF---NF---NF---NF-----F

- All of these will be in SCORE and SCORE+ but ONCE only

D-----NF----- (NFs)-----

- Only this person, who lives beyond 10 years, will be in SCORE+ and not in SCORE... and only ONCE even if he/she has multiple events but stays alive
- This means that the final multiplier will be small, probably about 1.3

The prediction of CVD morbidity and total events

- A fundamental problem is that, with present methods, the “multiplier” will be dependent on the duration of follow up
- Clinicians observe that they see many more non-fatal than fatal events.
- But risk charts consider only the FIRST event, whether fatal or non-fatal
- Therefore, with a very long follow up, when everyone is dead, the multiplier is 1!
- The shorter the follow up, the higher the proportion of non-fatal events and the bigger the multiplier.

SCORE & HeartScore- update & new initiatives

3. BMI and HDL cholesterol-

Important but different effects on both risk estimation and management

**Alexandra Dudina and
Marie-Therese Cooney**

Summary

– BMI and HDL effect on CV risk

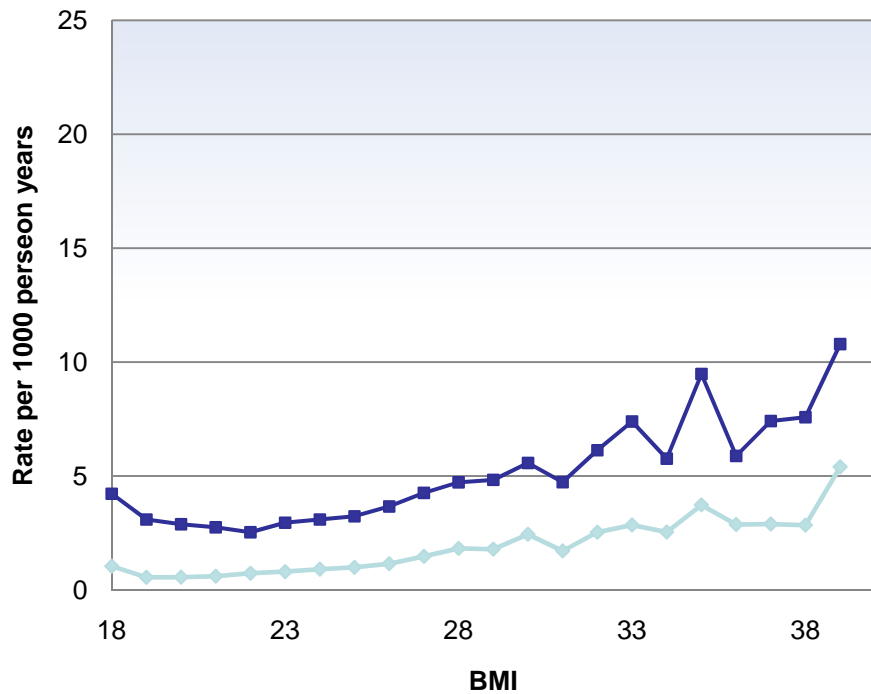

- BMI predicts both total and CVD mortality, especially in **younger** persons
- The effect is not independent of other risk factors, probably because its effect is partially or completely mediated through effects on other CV risk factors
- This does not reduce, but rather increases, the impact of elevated BMI on public health
- HDL cholesterol is an independent risk factor for CVD mortality in both genders, all ages, and in all strata of total CVD risk, including **older** women

Summary

– BMI and HDL in risk estimation

- HDL cholesterol can be incorporated as an additional variable in risk estimation. Easier using a electronic system- HeartSCORE
- Inclusion results in only minor changes in risk estimate for the entire population
- But important for the individual – especially those at intermediate risk levels and with unusually high or low HDL cholesterol levels
- Appropriate incorporation of BMI into risk estimation could be an a surrogate for other risk factors
- A simple system, using only easily measured variables, would make risk estimation more accessible and cost effective

Women - CVD + total mortality rates

Men - CVD + total mortality rates

SCORE BMI

An increase in BMI from 20 to 30 is associated with-

- **0.75 mmol/L** increase in cholesterol
- **0.2 mmol/L** decrease in HDL chol
- An increase in Chol:HDL chol ratio from **4** to **5.5**
- **15 mmHg** increase in blood pressure
- A **doubling** of cardiovascular mortality; more marked in the young and in women

CVD Mortality Rate Relative Risks Compared to the lowest total Chol Quartile and the highest HDL quartile

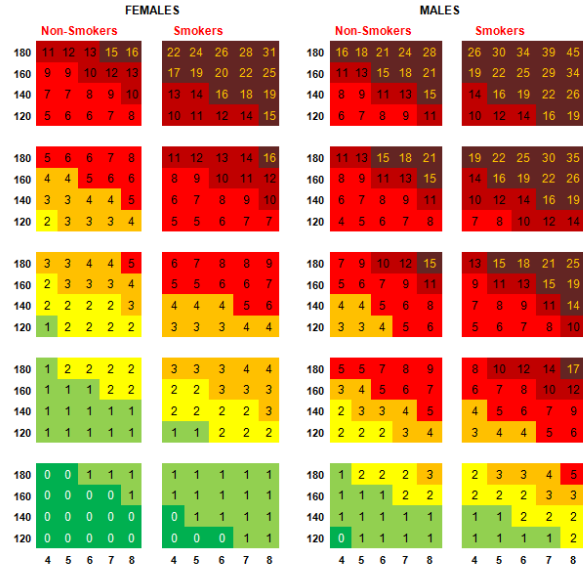

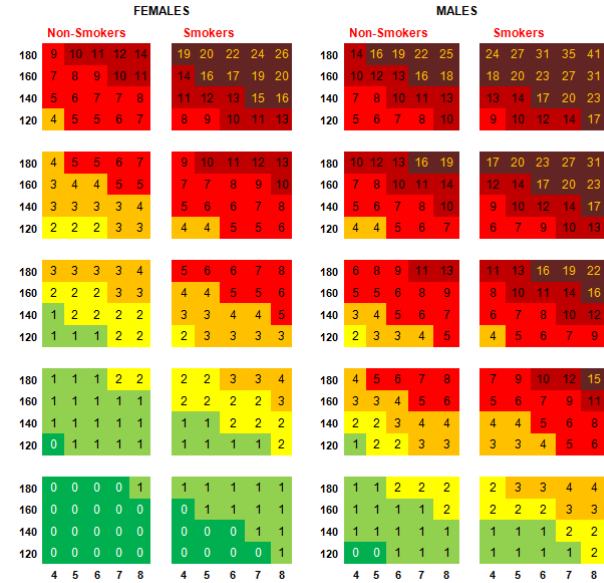

Chart for Women from high risk countries

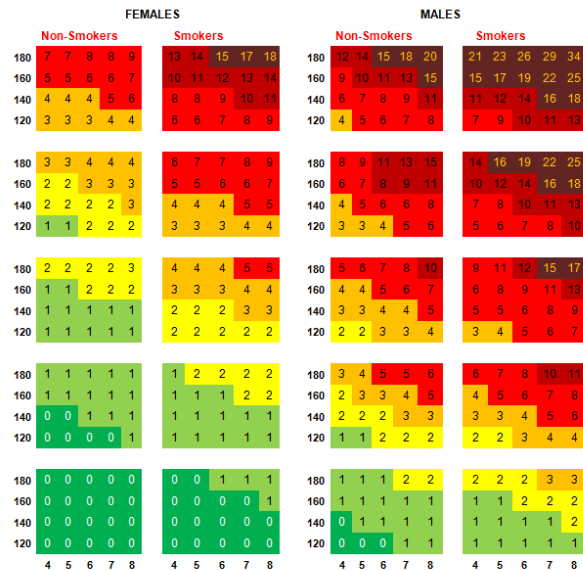

HDL = 0.8mmol/l

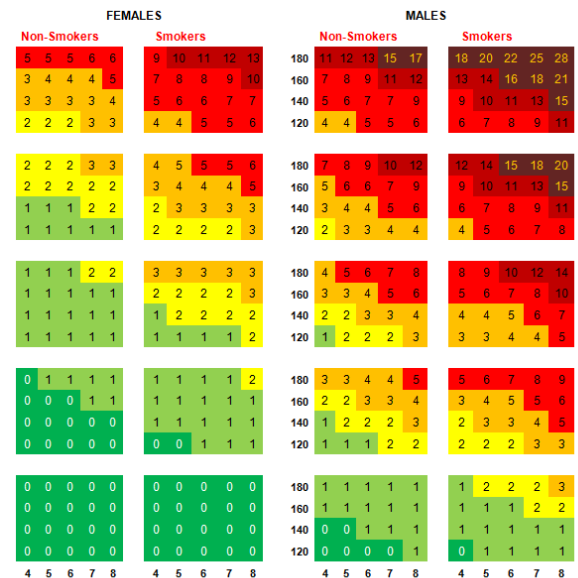

HDL = 1.0mmol/l

HDL = 1.4mmol/l

HDL = 1.8mmol/l

SCORE & HeartScore- update & new initiatives

4.Simplifying Risk estimation-

What can you achieve with age, gender, smoking and BMI alone?

Simplifying Risk Estimation

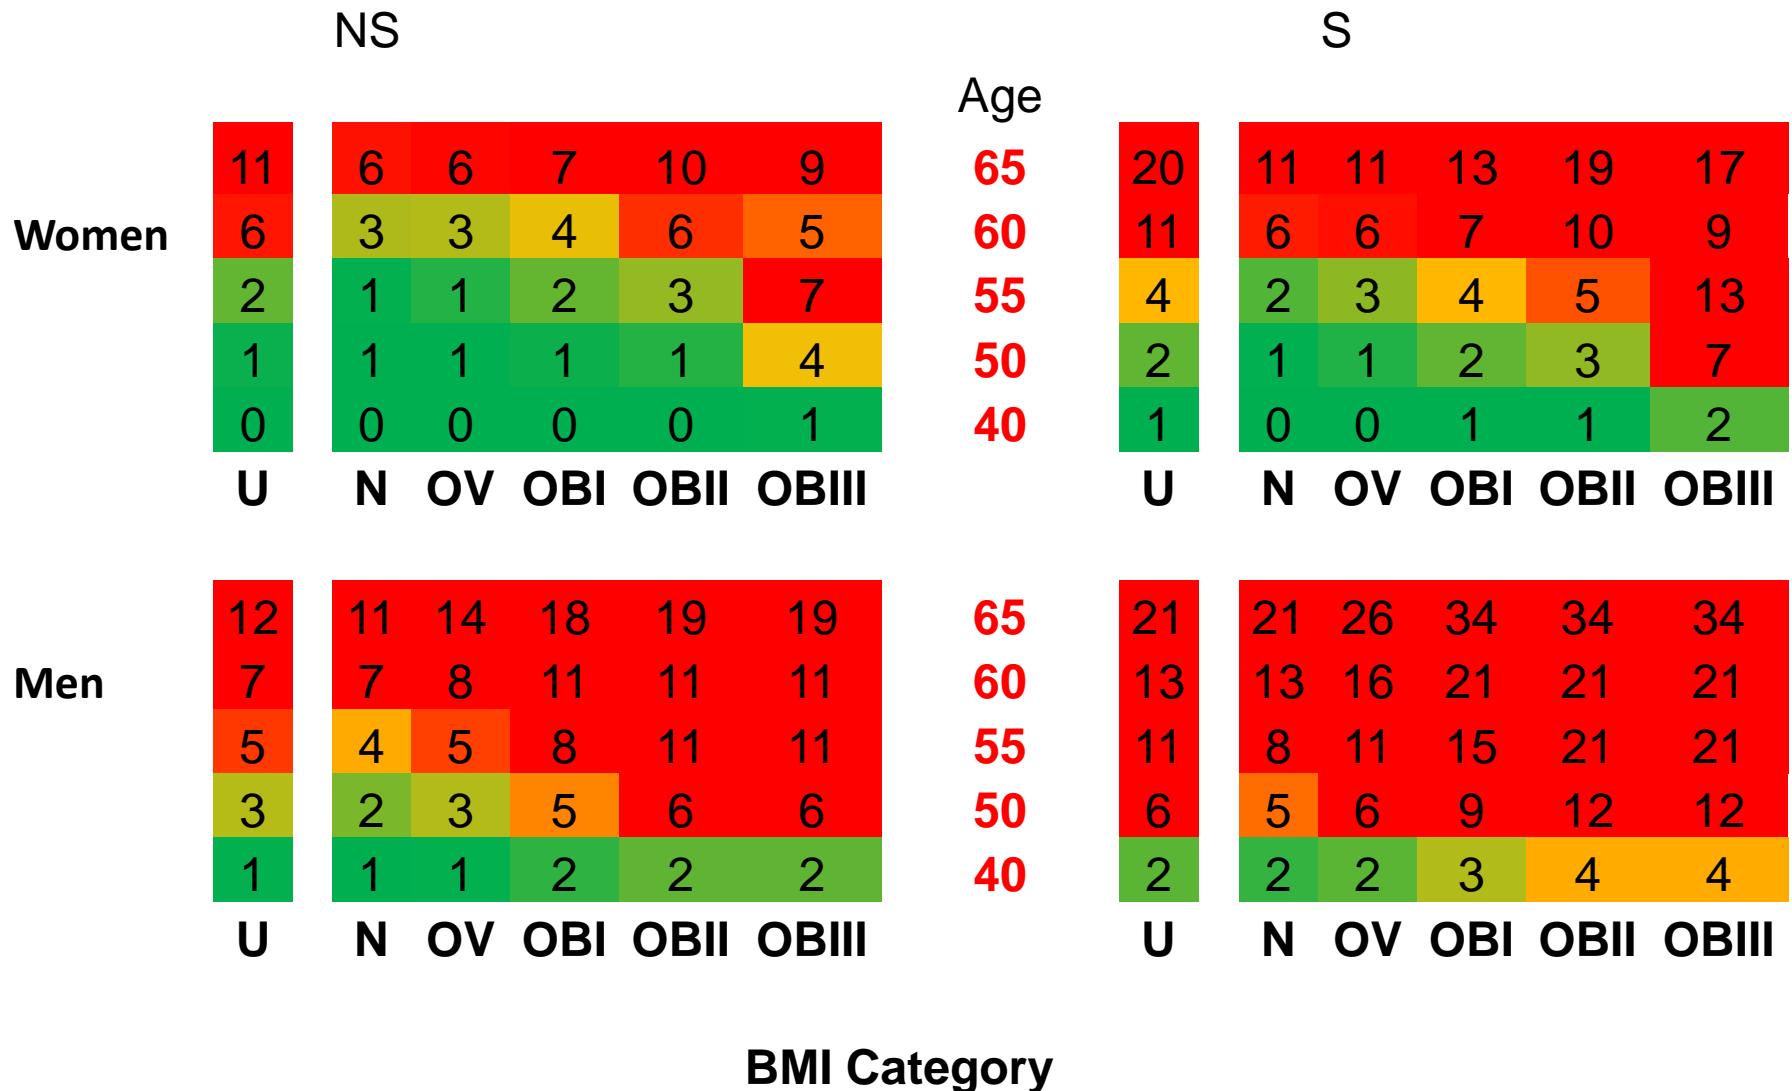

- **Estimating risk without laboratory measurements**
- **Or without blood pressure measurement**
- **Makes process more accessible and cost effective**
- **Particularly useful in regions where access to medical facilities is limited.**

SCORE BMI

- Objective: To develop a simple risk estimation chart, based on the SCORE dataset, for the estimation of ten year risk of CVD mortality using only simple non laboratory, non clinic based measurements – age, gender, smoking status and BMI (in categories)

SCORE BMI Charts – **Not finalised**

for use in high risk European Regions

SCORE & HeartScore- update & new initiatives

5. Heart Rate-

Will it add anything?

Heart rate Project

Objectives:

1. To examine the risk associated with resting heart rate in a general population
2. To derive a risk estimation function including heart rate as an additional variable & test whether this results in improved risk estimation

Heart rate Project: Summary Results

Effects of heart rate on endpoints:

- Independent risk factor – men and women
- Remains after exclusion of events occurring in the first 2 years of follow-up
- Stronger effect on fatal than non-fatal endpoints
- Effect is mainly on coronary mortality, with little effect of cerebrovascular endpoints
- The effect of heart rate weakens with increasing follow-up time
- The effect is independent of other co-morbidities and physical activity level (self-reported)

Heart rate Project: Summary **Results**

Incorporation of heart rate in risk estimation systems

- No meaningful improvement in discrimination when heart rate is included in risk estimation systems including the current SCORE variables.
 - Assessed using both AUROC and net reclassification indices
- Useful improvement in discrimination when heart rate is added to simple risk estimation system containing only age, gender, BMI and smoking status.

Discrimination of the simple function with and without heart rate included

	Men		Women	
	Simple Score with RHR	Simple Score without RHR	Simple Score with RHR	Simple Score without RHR
AUROC	0.8196	0.8121, p=0.036	0.8667	0.8547, p=0.018

Incorporation of heart rate in the simple function also resulted in an improvement in reclassification with a net reclassification index of 0.14, $p < 0.01$

SCORE & HeartScore- update & new initiatives

6. Risk in the old-

Risk factors function differently in old people and we suspect that risk estimation can be improved

SCORE ELD

Objective:

- To derive a risk estimation function specifically from data from the older age group (> 65 years)
- We hypothesise that this will result in improved risk estimation in the elderly because in other systems use the same beta coefficients for the risk factors for all age groups – and it is known that risk factors function differently in the elderly

SCORE ELD - Progress

- Additional data has been received from Norwegian collaborators in order to increase the numbers in the older age group for the derivation dataset.
- The function has been derived.
- Currently working on internal validation of the function
- External validation of this function will be an important aspect

HeartSCORE

- The electronic, interactive version of SCORE
- Available on line, as a downloadable, stand-alone version, and on CD
- Can interact to adjust targets, calculate risk at different levels of risk factors
- Will include more variables such as HDL cholesterol and BMI
- Links into advice from the pocket guidelines
- Simple graphic of risk and risk factor advice can be printed out for the patient
- www.HeartScore.org

HeartScore⁺[®]

The electronic, interactive
tool for predicting &
managing the risk of heart
attack and stroke in Europe

Now stand-alone and web-based with
country-specific versions

HeartScore[®] Benefits

- 1 allows quick & easy risk estimation
- 2 graphical display of absolute CVD risk
- 3 identifies relative impact of modifiable risk factors
- 4 helps optimise potential benefits of intervention
- 5 leads physician to relevant information in electronic guidelines
- 6 prints tailored health advice based on patient's risk profile

**encourages behavioural
change and compliance
to treatment**

HeartScore Update

- **Adapted to 2007 European Guidelines on CVD Prevention**
(incl. relative risk for younger patients)
- **13 versions available in 15 languages**
 - 2 European (high & low)
 - 7 Country-specific (Cyprus, Germany, Greece, Poland, Spain, Sweden, Slovakia, Czech Republic)
 - 3 Translated (Bosnia & Herzegovina, Russia, Romania)
- **12,668** unique users
 - 77,49% EU
 - 22,51 non-EU
 - Mostly cardiologists, trainee cardiologists, GPs and nurses
- Available formats: web-based, PC, online quick calculator
- Downloadable PC versions: European, Sweden and Slovakia
- Average number of new users per month: 270

Progression per version

Future national versions development in 2009

- Spain (calibrated PC) – ESC
Congress Barcelona
- Slovenia
- Turkey
- Estonia

SCORE and HeartScore

An update

SUMMARY

- 1. JTF4 continues to stress total risk estimation**
- 2. The SCORE risk estimation system is based on a large data set that is representative of Europe and/or is very simple**
- 3. Relative risk charts aid in advising younger persons. Risk age may be added**
- 4. Total event charts being tested; difficult and unstable and the multiplier may be much less than expected**
- 5. BMI and HDL cholesterol contribute to risk evaluation, but in different ways**
- 6. A simple chart based on age, gender, smoking and BMI only is possible. Heart rate may contribute usefully**
- 7. It is likely that calculating risk separately for older persons will improve risk estimation**
- 8. HeartScore has the flexibility to accommodate these advances**

Thank you
