THROMBOEMBOLISM

Refining Clinical Risk Stratification for Predicting Stroke and Thromboembolism in Atrial Fibrillation Using a Novel Risk Factor-Based Approach

The Euro Heart Survey on Atrial Fibrillation

Gregory Y. H. Lip, MD; Robby Nieuwlaat, PhD; Ron Pisters, MD; Deirdre A. Lane, PhD; and Harry J. G. M. Crijns, MD

Background: Contemporary clinical risk stratification schemata for predicting stroke and thromboembolism (TE) in patients with atrial fibrillation (AF) are largely derived from risk factors identified from trial cohorts. Thus, many potential risk factors have not been included.

Methods: We refined the 2006 Birmingham/National Institute for Health and Clinical Excellence (NICE) stroke risk stratification schema into a risk factor-based approach by reclassifying and/or incorporating additional new risk factors where relevant. This schema was then compared with existing stroke risk stratification schema in a real-world cohort of patients with AF (n = 1,084) from the Euro Heart Survey for AF.

Results: Risk categorization differed widely between the different schemes compared. Patients classified as high risk ranged from 10.2% with the Framingham schema to 75.7% with the Birmingham 2009 schema. The classic $CHADS_2$ (Congestive heart failure, Hypertension, Age > 75, Diabetes, prior Stroke/transient ischemic attack) schema categorized the largest proportion (61.9%) into the intermediate-risk strata, whereas the Birmingham 2009 schema classified 15.1% into this category. The Birmingham 2009 schema classified only 9.2% as low risk, whereas the Framingham scheme categorized 48.3% as low risk. Calculated C-statistics suggested modest predictive value of all schema for TE. The Birmingham 2009 schema fared marginally better (C-statistic, 0.606) than $CHADS_2$. However, those classified as low risk by the Birmingham 2009 and NICE schema were truly low risk with no TE events recorded, whereas TE events occurred in 1.4% of low-risk $CHADS_2$ subjects. When expressed as a scoring system, the Birmingham 2009 schema (CHA_2DS_2-VASc acronym) showed an increase in TE rate with increasing scores (*P* value for trend = .003).

Conclusion: Our novel, simple stroke risk stratification schema, based on a risk factor approach, provides some improvement in predictive value for TE over the $CHADS_2$ schema, with low event rates in low-risk subjects and the classification of only a small proportion of subjects into the intermediate-risk category. This schema could improve our approach to stroke risk stratification in patients with AF.

My question

What does this all mean??

ATRIAL FIBRILLATION

Cryptogenic stroke—can we abandon this apologetic diagnosis?

A. John Camm

Cryptogenic stroke is an apology for ignorance about the cause of ischaemic stroke. Now, in two new studies involving long-term electrocardiogram monitoring, investigators from the EMBRACE and CRYSTAL-AF trials suggest that many instances of cryptogenic stroke might be caused by undetected atrial fibrillation.

Camm, A. J. *Nat. Rev. Cardiol.* **11**, 504–505 (2014); published online 29 July 2014; doi:10.1038/nrcardio.2014.111

Sudden occlusion of an artery supplying the brain can lead to embolic stroke or transient ischaemic attack (TIA). However, many embolic strokes remain unexplained and are described as 'cryptogenic', one of many words (such as essential, primary, lone, and idiopathic) that we use to disguise our ignorance of the underlying cause. In two new studies, in which the potential causes of cryptogenic stroke were investigated, the researchers of the EMBRACE[1] and CRYSTAL-AF[2] trials unequivocally demonstrate that prolonged electrocardiogram (ECG) monitoring reveals more atrial fibrillation than standard 12-lead ECG or 24-h or 48-h Holter ECG protocol, and conclude that these arrhythmias were a likely cause of embolic stroke or TIA.

Ischaemic events might result from a number of different mechanisms, such as a dislodged thrombus, or rarely a tumour, from the atrium or ventricle, or a detachment of atheromatous debris from the aorta or arterial vessels that lead to the brain. Similarly, embolism of a venous thrombus or air through an atrial septal defect or patent foramen ovale into the arterial circulation can also lead to an ischaemic event. However, the most-commonly diagnosed cause of ischaemic stroke is atrial fibrillation, which can lead to the formation of a blood clot and its subsequent embolization, commonly in the left atrial appendage. Many investigators have suspected that atrial fibrillation, which is often undetected and an intermittent arrhythmia, might cause many unexplained ischaemic strokes.[3,4] In some studies, repeated 12-lead ECGs and additional ambulatory ECG monitoring for ≥24 h can reveal atrial fibrillation in a substantial proportion of patients within hours or days of the embolic event.[5] Physicians have, therefore, been easily satisfied that this atrial fibrillation was relevant to the pathophysiology of stroke, and consequently initiated anticoagulant rather than antiplatelet therapy to prevent a recurrence.

However, about one-quarter of embolic strokes remain unexplained, and other studies have shown that atrial fibrillation can be highly transient, ephemeral, and silent.[6,7] Physicians have struggled with the diagnostic inadequacy of momentary ECG recordings. Continuous and sustained ECG readings might, therefore, be needed to uncover the arrhythmia. When new and robust ECG-monitoring techniques became available, trials were initiated with these new technologies to explore the possibility that the left atrium was the source of a greater proportion of embolic strokes that previously recognised.

The investigators in both the EMBRACE and CRYSTAL-AF studies used the standard definition of atrial fibrillation, which was developed specifically to reveal whether the arrhythmia can occur after an ablation procedure. However, whether a 30 s episode of atrial fibrillation has any mechanistic influence on thrombus formation is unclear.[8] Gladstone and colleagues (EMBRACE)[1] used continuous surface ECG monitoring for 30 days, whereas Sanna *et al.* (CRYSTAL-AF)[2] implanted miniature ECG monitors beneath the skin and monitored heart rhythm for up to 3 years after the initial stroke. The monitoring periods in both trials took place on average well after the stroke had occurred (Table 1). Can one realistically infer from an episode of atrial fibrillation occurring at some interval after the embolic event that this arrhythmia explained its occurrence? My opinion is that one should be reasonably sceptical. Nonetheless, many of the recorded episodes were not remote from the index event and might, therefore, provide at least a clue about events that precipitated the stroke. In the EMBRACE trial,[1] Gladstone and colleagues report that only half of the cases of atrial fibrillation were detected in the first week after the stroke, and the remainder occurred over the next 3 weeks. Whereas in the CRYSTAL-AF study,[2] which was conducted over 3 years, cases arose throughout the recording period. Moreover, neither trial included a control group of patients who had not sustained an ischaemic stroke or TIA against which to judge the relevance of the recorded arrhythmia. The studies were not configured to investigate the prognostic importance of the atrial fibrillation in terms of subsequent stroke or TIA recurrence because physicians were free to act on the ECG diagnosis, and their interventions would have compromised any possible conclusion.

No-one would disagree with the conclusions made by both teams of investigators that atrial fibrillation was the underlying cause of the observed cryptogenic stoke

Table 1 | Comparison of the EMBRACE[1] and CRYSTAL-AF[2] trials

Study	Investigation group	*n*	Onset of monitoring after stroke (days)	Duration of monitoring (days)	Proportion with AF (%)
EMBRACE[1]	Usual*	285	75.1±38.6	90	3.2
	Intensive‡	286			16.1
CRYSTAL-AF[2]	Usual*	220	38.1±27.6	~180	1.4
	Intensive§	221			8.9

*12-lead ECG and Holter ECG monitoring for 24–48 h. ‡Continuous surface ECG for 4 weeks. §Subcutaneous ECG monitoring with an implanted device for up to 3 years. Abbreviations: AF, atrial fibrillation; ECG, electrocardiogram.

Drug and Ablative Therapies

Summary of Recommendations for Risk-Based Antithrombotic Therapy

Recommendations	COR	LOE	References
Antithrombotic therapy based on shared decision making, discussion of risks of stroke and bleeding, and patient's preferences	I	C	N/A
Selection of antithrombotic therapy based on risk of thromboembolism	I	B	64–67
CHA_2DS_2-VASc score recommended to assess stroke risk	I	B	68–70
Warfarin recommended for mechanical heart valves and target INR intensity based on type and location of prosthesis	I	B	71–73
With prior stroke, TIA, or CHA_2DS_2-VASc score ≥2, oral anticoagulants recommended. Options include:			
Warfarin	I	A	68–70
Dabigatran, rivaroxaban, or apixaban	I	B	74–76
With warfarin, determine INR at least weekly during initiation of therapy and monthly when stable	I	A	77–79
Direct thrombin or factor Xa inhibitor recommended if unable to maintain therapeutic INR	I	C	N/A
Reevaluate the need for anticoagulation at periodic intervals	I	C	N/A
Bridging therapy with UFH or LMWH recommended with a mechanical heart valve if warfarin is interrupted. Bridging therapy should balance risks of stroke and bleeding	I	C	N/A
For patients without mechanical heart valves, bridging therapy decisions should balance stroke and bleeding risks against duration of time patient will not be anticoagulated	I	C	N/A
Evaluate renal function before initiation of direct thrombin or factor Xa inhibitors, and reevaluate when clinically indicated and at least annually	I	B	80–82
For atrial flutter, antithrombotic therapy is recommended as for AF	I	C	N/A
With nonvalvular AF and CHA_2DS_2-VASc score of 0, it is reasonable to omit antithrombotic therapy	IIa	B	80,81
With CHA_2DS_2-VASc score ≥2 and end-stage CKD (CrCl <15 mL/min) or on hemodialysis, it is reasonable to prescribe warfarin for oral anticoagulation	IIa	B	82
With nonvalvular AF and a CHA_2DS_2-VASc score of 1, no antithrombotic therapy or treatment with oral anticoagulant or aspirin may be considered	IIb	C	N/A
With moderate-to-severe CKD and CHA_2DS_2-VASc scores ≥2, reduced doses of direct thrombin or factor Xa inhibitors may be considered	IIb	C	N/A
For PCI,* BMS may be considered to minimize duration of DAPT	IIb	C	N/A
After coronary revascularization in patients with CHA_2DS_2-VASc score ≥2, it may be reasonable to use clopidogrel concurrently with oral anticoagulants but without aspirin	IIb	B	83
Direct thrombin dabigatran and factor Xa inhibitor rivaroxaban are not recommended in patients with AF and end-stage CKD or on dialysis because of a lack of evidence from clinical trials regarding the balance of risks and benefits	III: No Benefit	C	74–76, 84–86
Direct thrombin inhibitor dabigatran should not be used with a mechanical heart valve	III: Harm	B	87

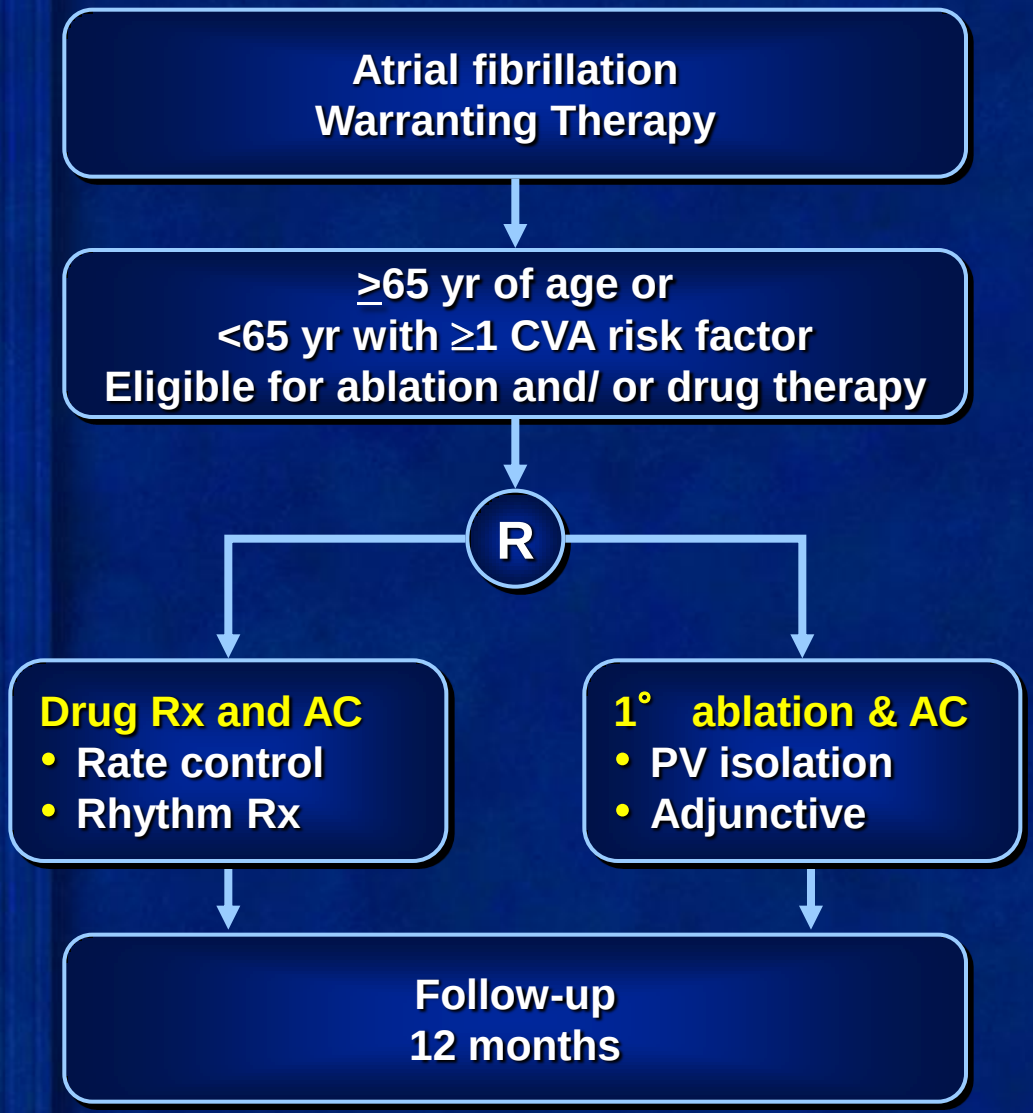
Design of the CABANA Study



Inclusion Criteria

- ≥2 paroxysmal AF episodes (≥1 hour) over 4 mos or ≥1 persistent AF episode (>1 week)
- ≥65 yr of age, or <65 yr with ≥1 risk factors
  - Hypertension
  - Diabetes
  - Heart failure
  - Prior CVA or TIA
  - LA size >5.0 cm (Vol In ≥40 cc/m^2)
  - EF ≤35 %
- Eligible for ablation and ≥2 rhythm control and/or ≥3 rate control drugs

CABANA Pilot Study; ACC 2010
