Post-ischemic neovascularization:

basic concept and new treatment options

Professor Costanza Emanueli, PhD

British Heart Foundation Senior Research Fellow

Professor and Chair of Vascular Pathology and Regeneration- Bristol

Visiting Professor -ICL

ESC Summer school, Nice 16 June 2013

Index of this Lecture

- Introduction to ischemia and post-ischemic neovascularisation
- Research Models
- Therapeutic angiogenesis research: past, present and future
- microRNAs in post-ischaemic vascular regeneration
- Novel stem cell products: Empowered EPCs, Pericyte progenitor cells

Ischemic Disease

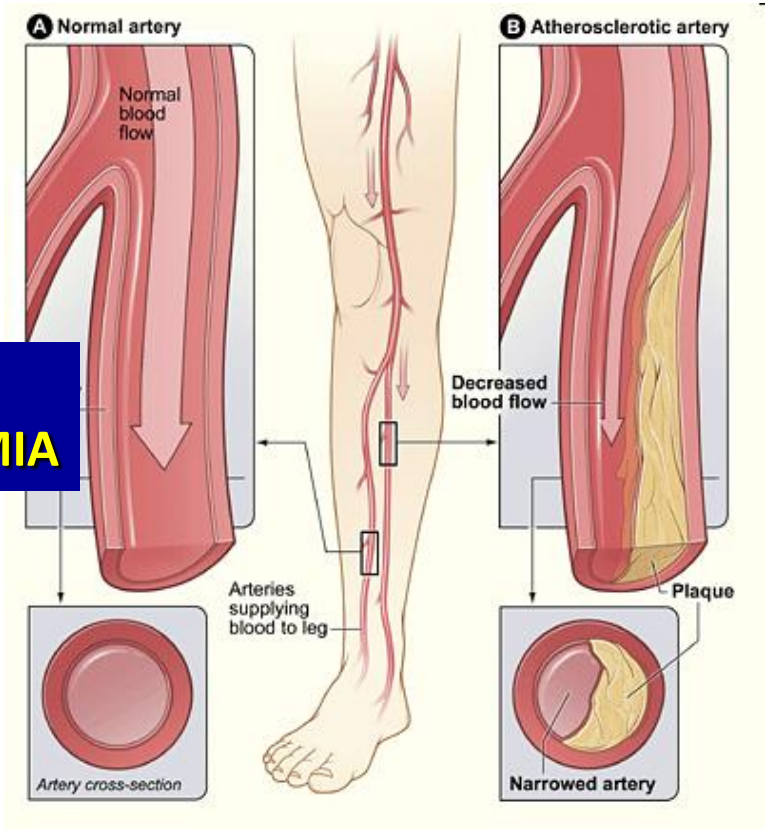
- Tissue ischaemia is caused by poor blood flow supply, which impairs the delivery of oxygen (creating hypoxia) and nutrients (creating tissue starvation)

- Ischaemic disease is favoured by atherosclerosis, diabetes, aging and a series of cardiovascular risk factors

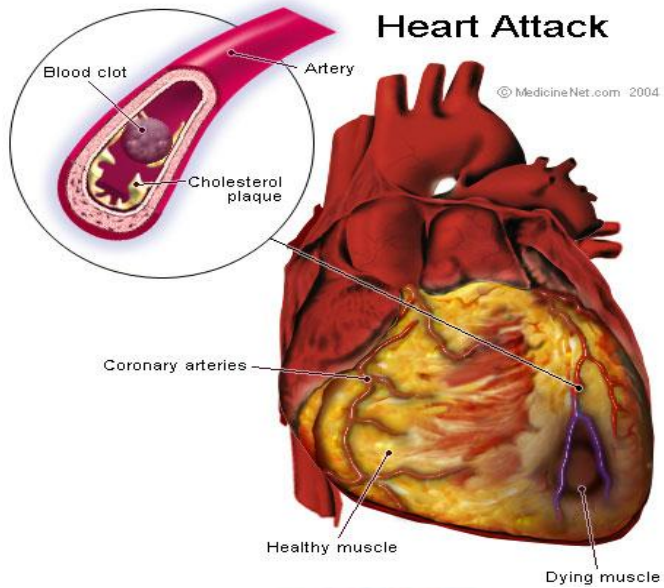
- Ischaemic disease is one of the biggest medical epidemic worldwide and its treatment is still an umet clinical need.

Post-Ischaemic Vascular Regeneration: the Medical Need

LIMB ISCHAEMIA

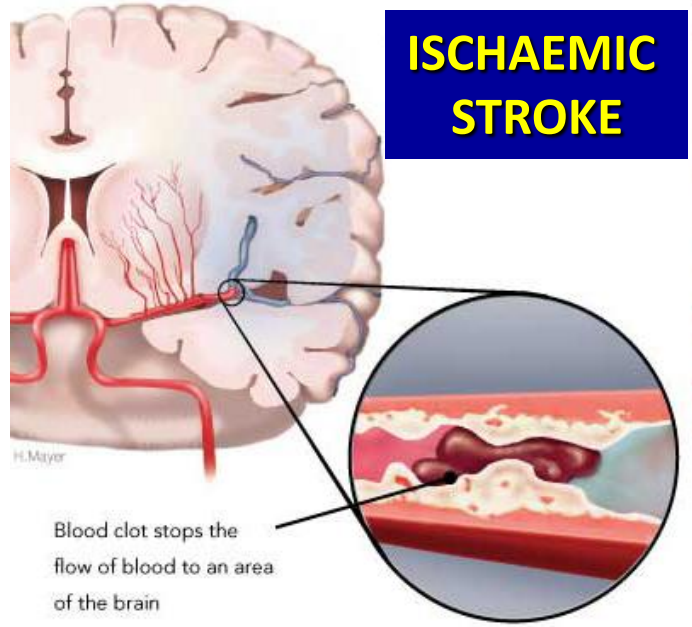


MYOCARDIAL INFARCT



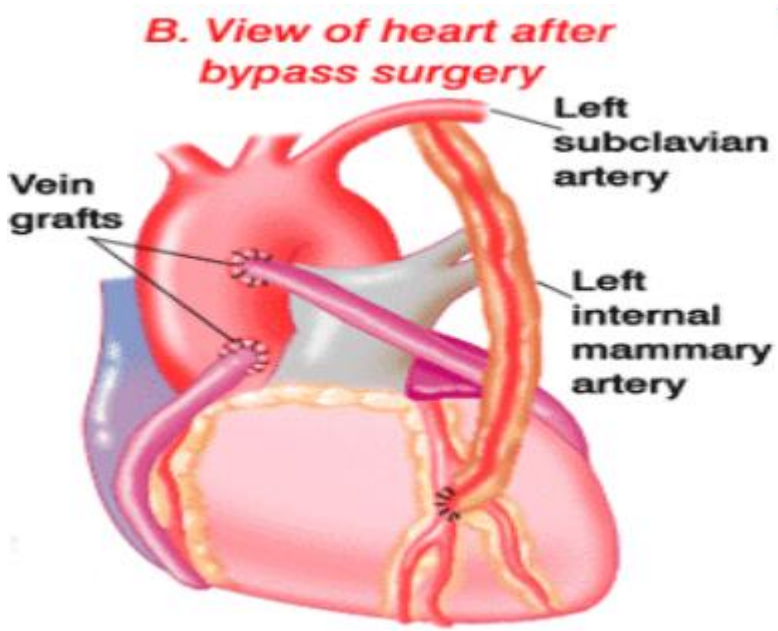
CRITICAL LIMB ISCHAEMIA

ISCHAEMIC STROKE



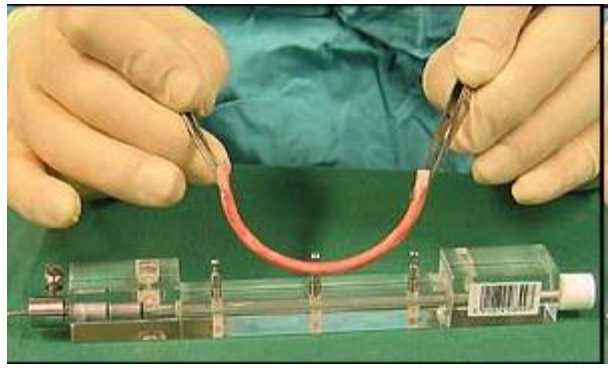
Vascular Regeneration: what can we try?

Substituting the diseased (large) vessel

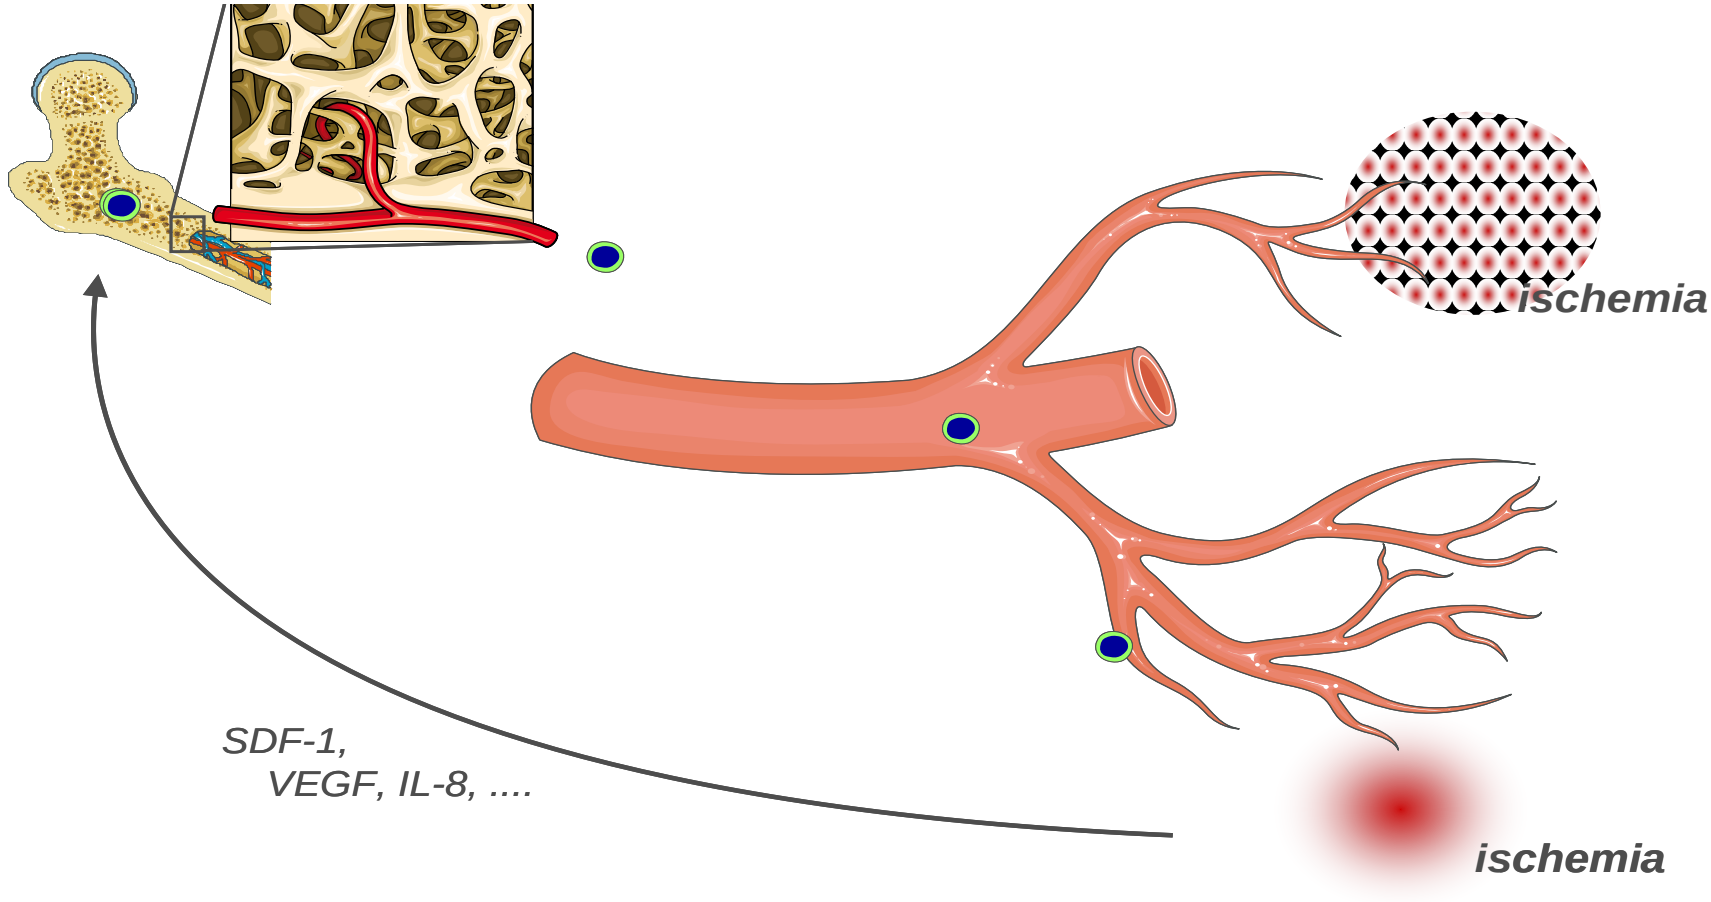


By-pass grafting with pieces of patient own vessels
(vena saphena and/or mammary artery)

By-pass grafting with “artificial” vessels created in the laboratory



Therapeutic Neovascularization



Strategies for Post-Ischemic Neovascularisation

- Increase the expression/activity of endogenous "pro-angiogenic" factors in ischemic tissues
- Contrast "anti-angiogenic" molecular signatures induced by pathology and/or risks factors
- Stimulate endogenous stem and progenitor cells with various pro-angiogenic capacities
- Transplantation of vascular stem and progenitor cells with pro-angiogenic capacities

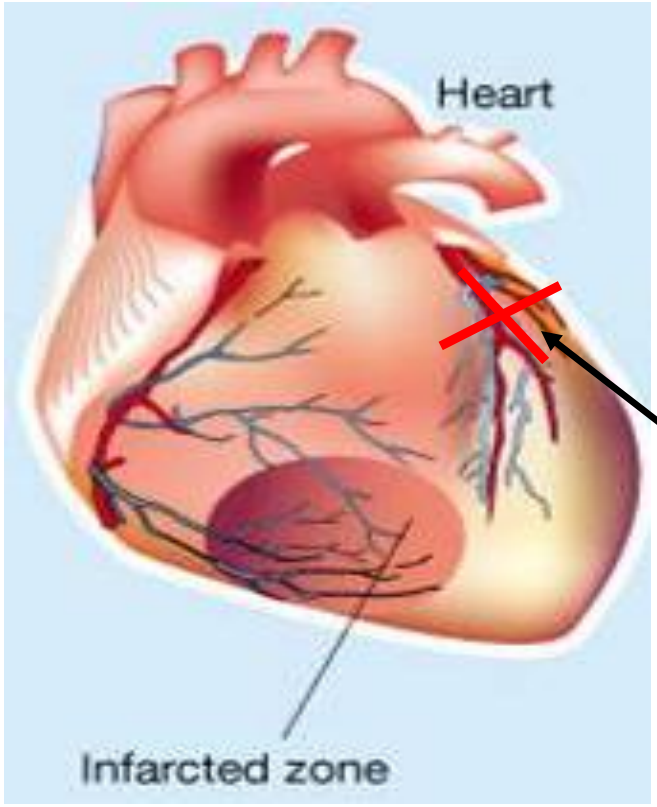
In Vivo Research Models

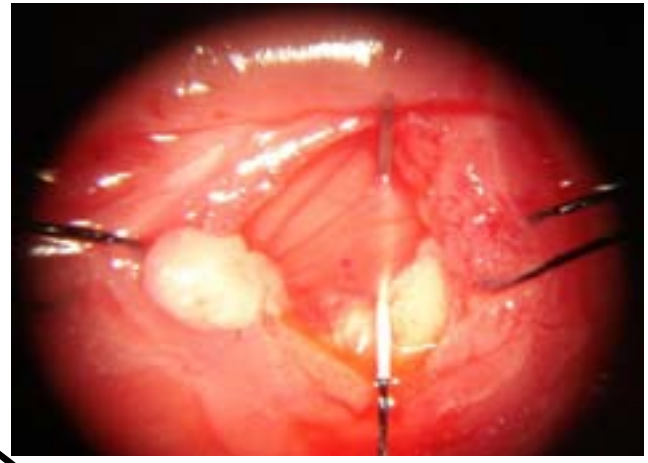
Animal Models of Ischemia: MI

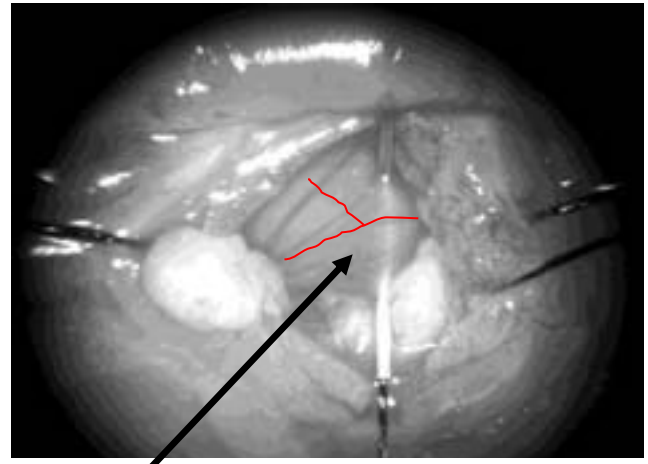
Experimental models of myocardial infarction (MI) are routinely performed in Rodents.

- Permanent ligation of LAD

- Ischemia/reperfusion





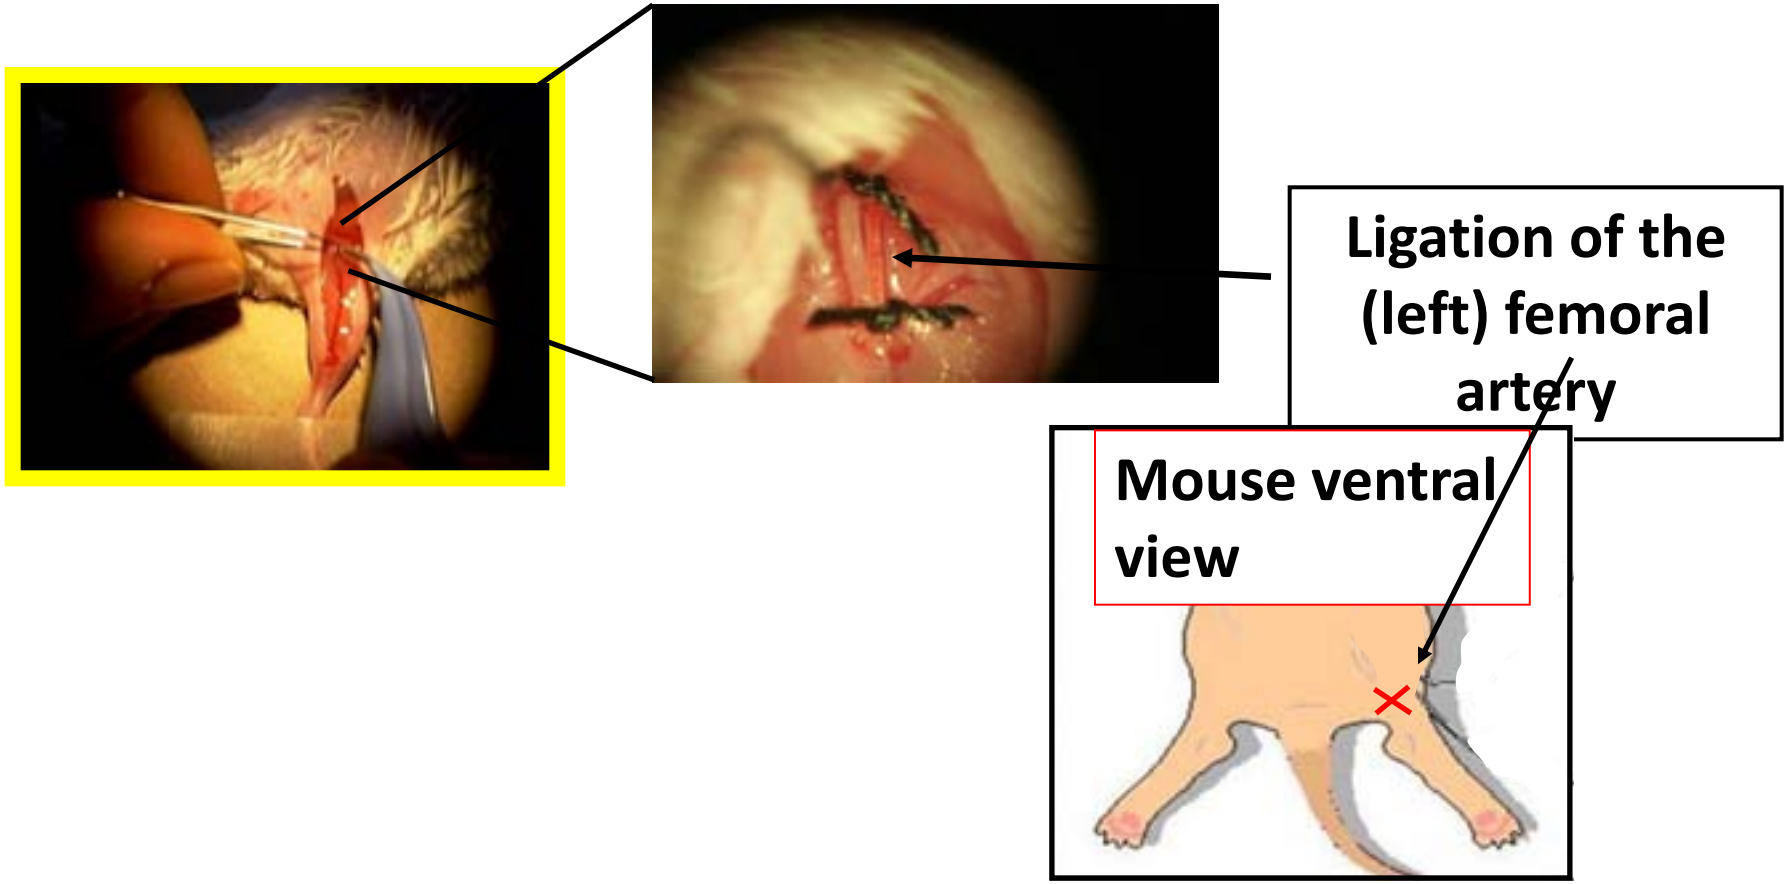


Occlusion of LAD

Mouse model of myocardial infarct

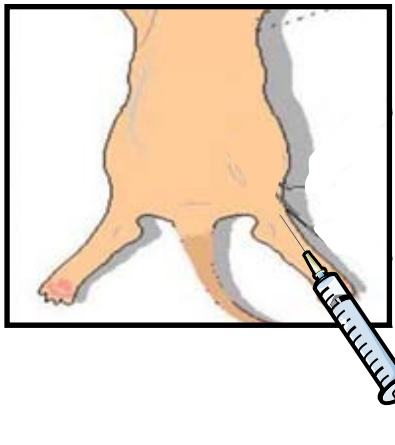
Animal Models of Ischemia: LI

Experimental models of limb ischemia (LI) is used in mice to mimic a situation comparable to peripheral artery disease. Since peripheral artery disease is often associated with diabetes, this model is also performed in diabetic mice. LI is performed by permanent ligation of one femoral artery.



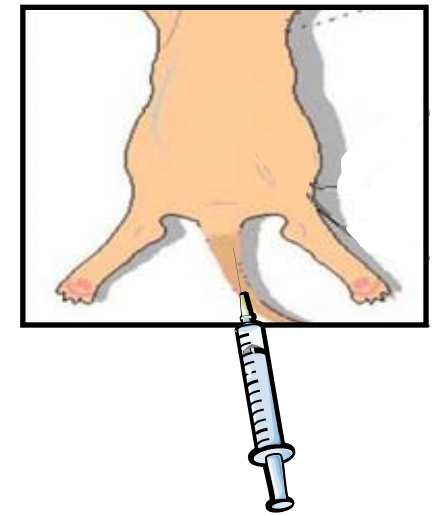
Systemic Gene/Cell Delivery

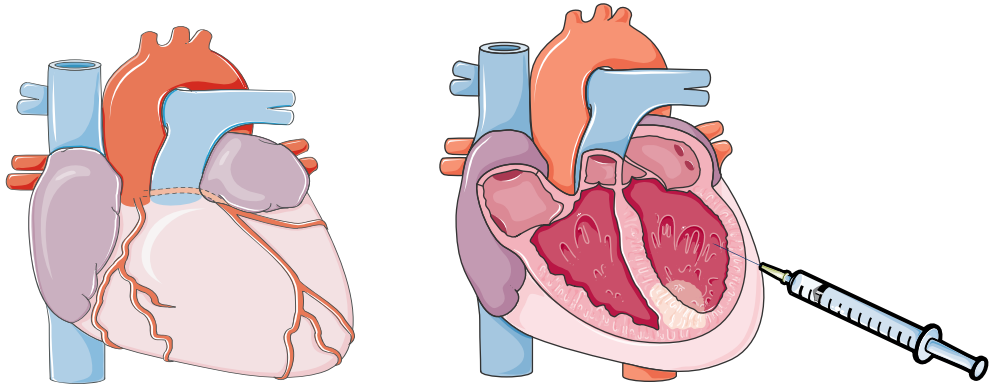
Intravenous infusion of stem cells/genes:



through the femoral vein

through the tail vein





through the left ventricular cavity

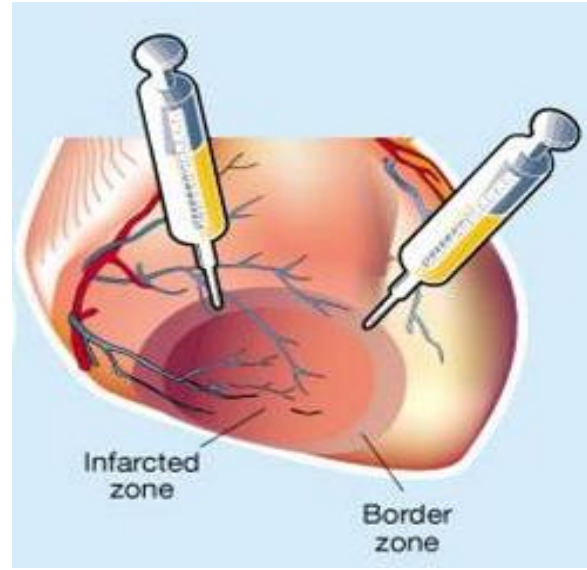
Limits of systemic delivery:

- Not possible to target a specific organ
- (Loss of cell number)
- (Loss of cell viability)

Local Gene/Cell Delivery

Cardiac:

1. **Endomyocardial needle injection**
2. **Catheter delivery (large animals)**
3. **Intracoronary infusion (large animals/humans)**
4. **Intrapericardial (large animals)**

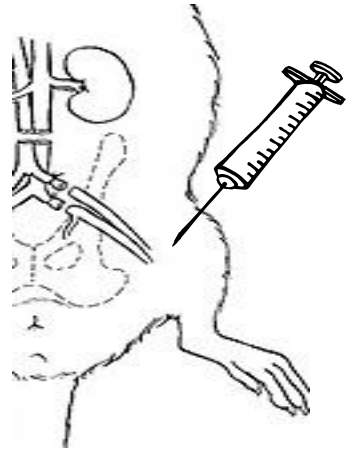


Cells/Genes are directly injected into the infarcted border zone

Injection is often performed immediately after MI

Lower limb

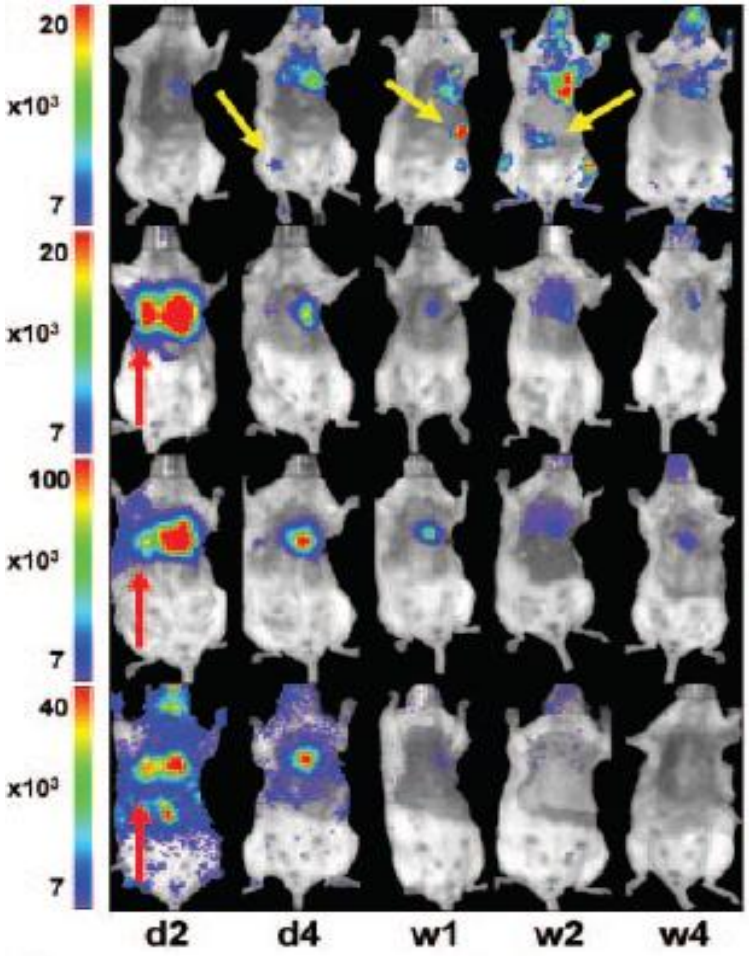
1. **Direct intramuscular injection**
2. **Intra-arterial infusion**



Cells/genes are directly injected into the adductor muscle often immediately after ischemia

Transgene/ Cell Tracking after Local Delivery

In vivo optical bioluminescence imaging (by using luminescence protein)



BM-derived mononuclear cells

Skeletal myoblasts

Mesenchymal stem cells

Fibroblasts

Types of injected stem cells

Body distribution of cells labelled with D-luciferin after intracardiac injection of different types of stem cells

Effect of fibroblast growth factor NV1FGF on amputation and death: a randomised placebo-controlled trial of gene therapy in critical limb ischaemia

Jill Belch, William R Hiatt, Iris Baumgartner, I Vickie Driver, Sigrid Nikol, Lars Norgren, Eric Van Belle, on behalf of the TAMARIS Committees and Investigators

Lancet 2011; 377: 1929–37

Published Online
May 31, 2011
DOI:10.1016/S0140-6736(11)60394-2

Summary

Background Patients with critical limb ischaemia have a high rate of amputation and mortality. We tested the hypothesis that non-viral 1 fibroblast growth factor (NV1FGF) would improve amputation-free survival.

Methods In this phase 3 trial (EFC6145/TAMARIS), 525 patients with critical limb ischaemia unsuitable for revascularisation were enrolled from 171 sites in 30 countries. All had ischaemic ulcer in legs or minor skin gangrene and met haemodynamic criteria (ankle pressure <70 mm Hg or a toe pressure <50 mm Hg, or both, or a transcutaneous oxygen pressure <30 mm Hg on the treated leg). Patients were randomly assigned to either NV1FGF at 0·2 mg/mL or matching placebo (visually identical) in a 1:1 ratio. Randomisation was done with a central interactive voice response system by block size 4 and was stratified by diabetes status and country. Investigators, patients, and study teams were masked to treatment. Patients received eight intramuscular injections of their assigned treatment in the index leg on days 1, 15, 29, and 43. The primary endpoint was time to major amputation or death at 1 year analysed by intention to treat with a log-rank test using a multivariate Cox proportional hazard model. This trial is registered with ClinicalTrials.gov, number NCT00566657.

Findings 259 patients were assigned to NV1FGF and 266 to placebo. All 525 patients were analysed. The mean age was 70 years (range 50–92), 365 (70%) were men, 280 (53%) had diabetes, and 248 (47%) had a history of coronary artery disease. The primary endpoint or components of the primary did not differ between treatment groups, with major amputation or death in 86 patients (33%) in the placebo group, and 96 (36%) in the active group (hazard ratio 1·11, 95% CI 0·83–1·49; p=0·48). No significant safety issues were recorded.

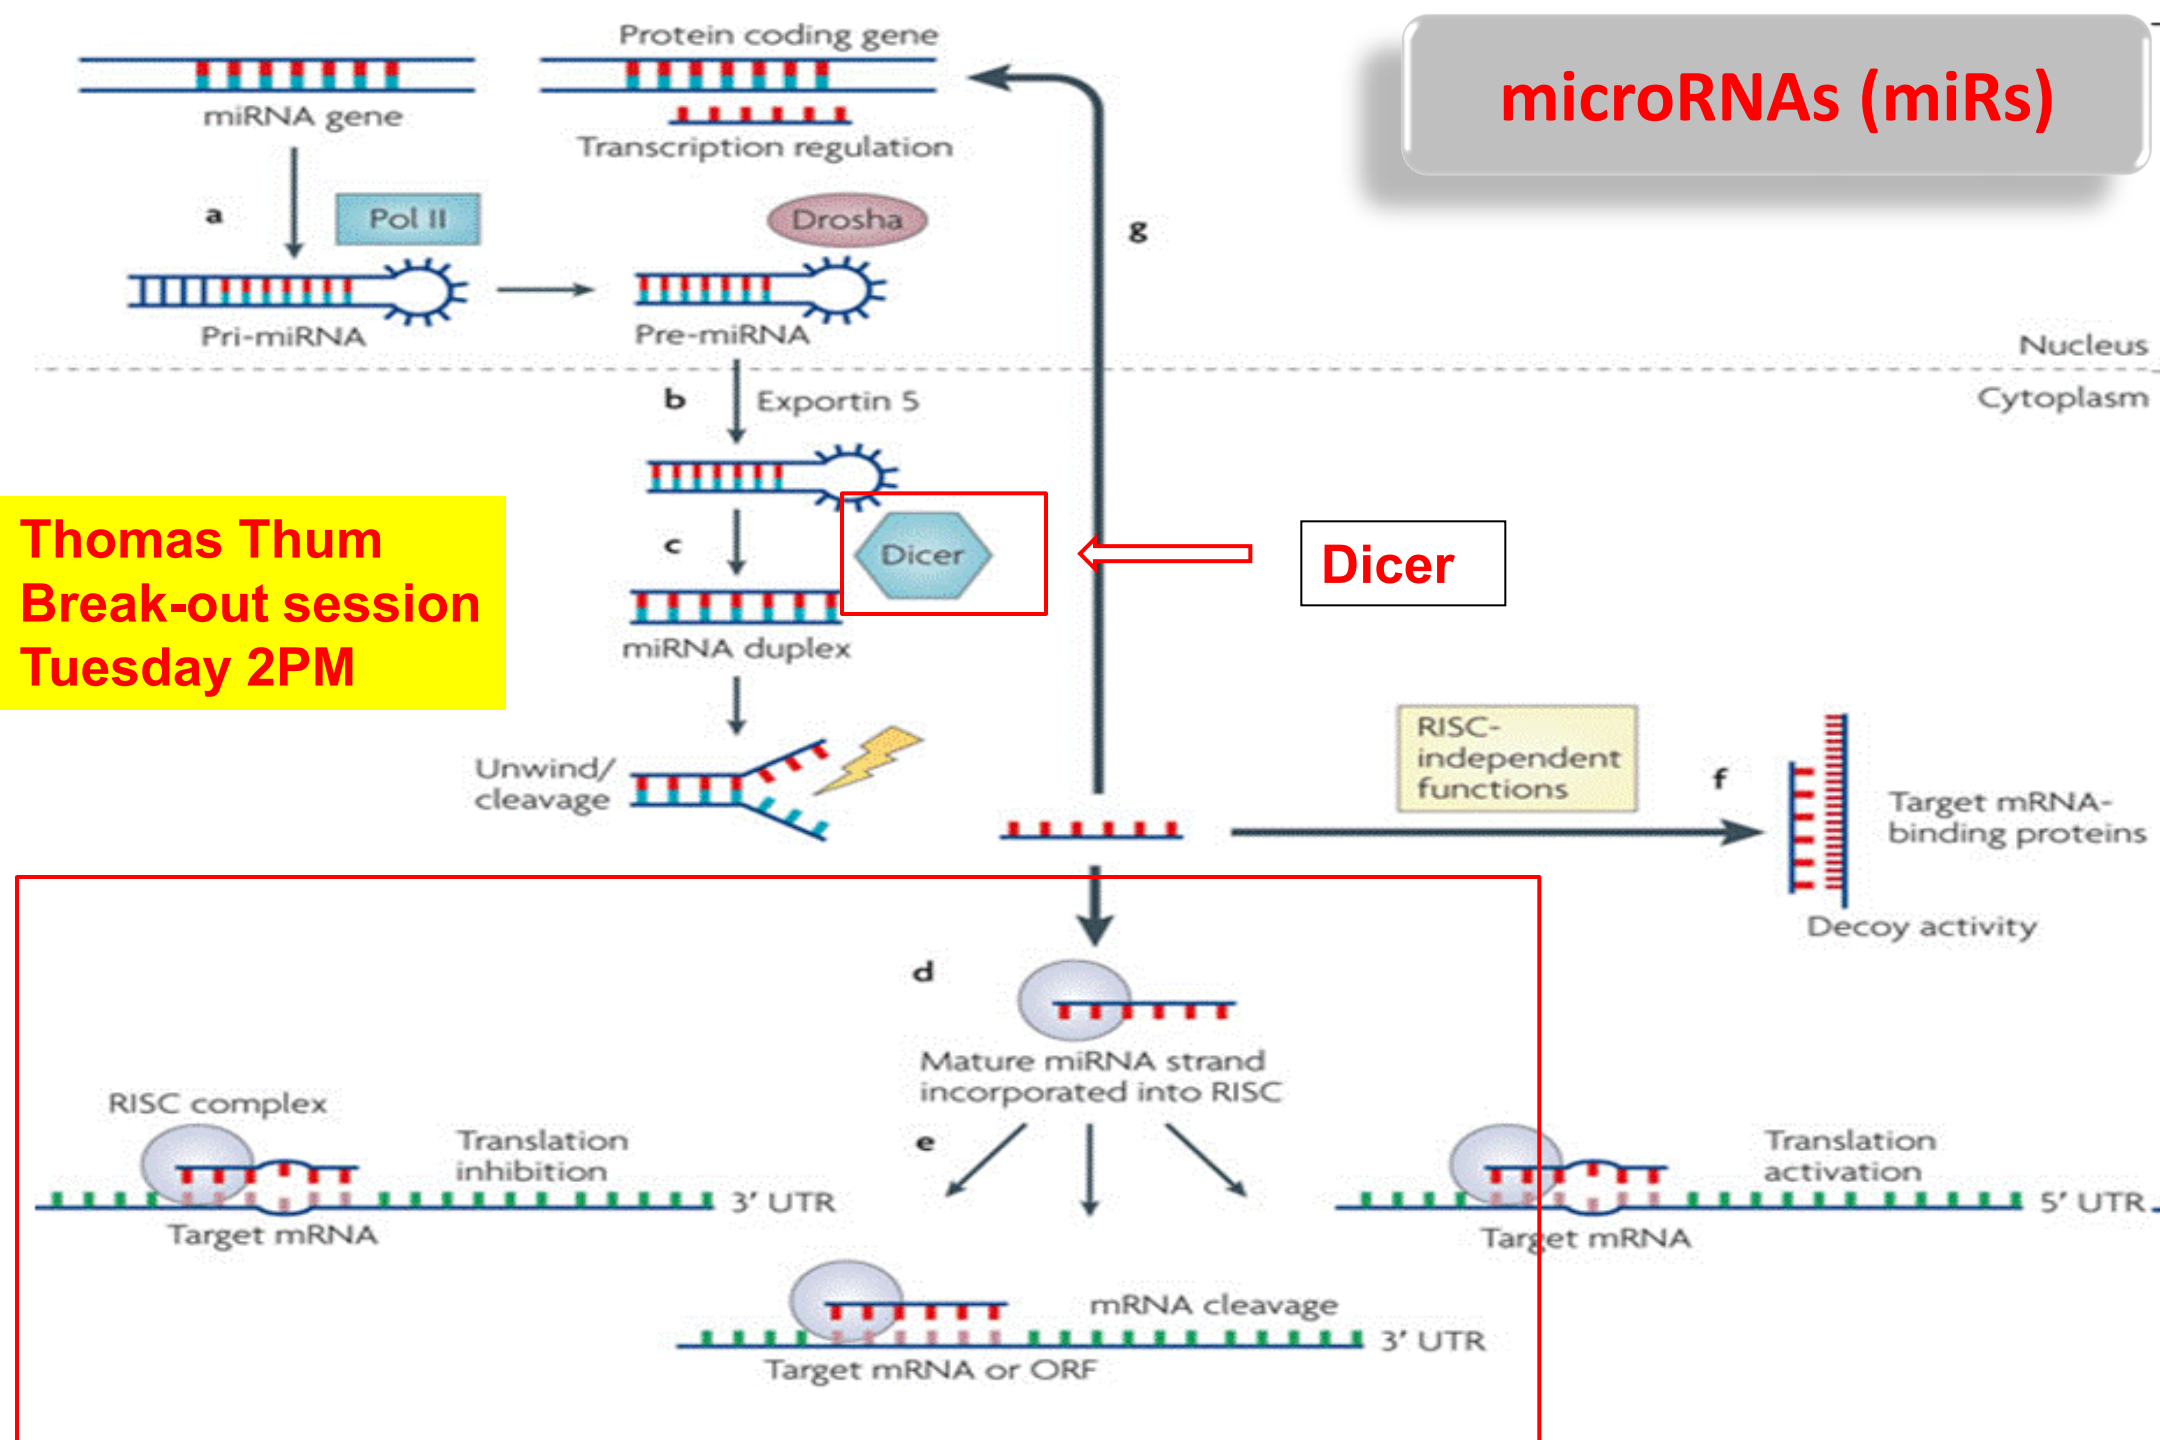
Interpretation TAMARIS provided no evidence that NV1FGF is effective in reduction of amputation or death in patients with critical limb ischaemia. Thus, this group of patients remains a major therapeutic challenge for the clinician.

Options for Improving Traditional Post-Ischaemic Neovascularisation Therapeutics

- More basic science to understand all the players in the angiogenesis and anti-angiogensis orchestras
- Test different angiogenesis modulator factors (growth factors and more)
- Combinatory approaches
- More severity in preclinical testing (large animal models, risk factors associated to experimental ischemia, etc)
- Work at gene vectors
- Success in *in vivo* small vessel imaging
- Design better clinical trials

- Do not give up!

microRNAs (miRs)

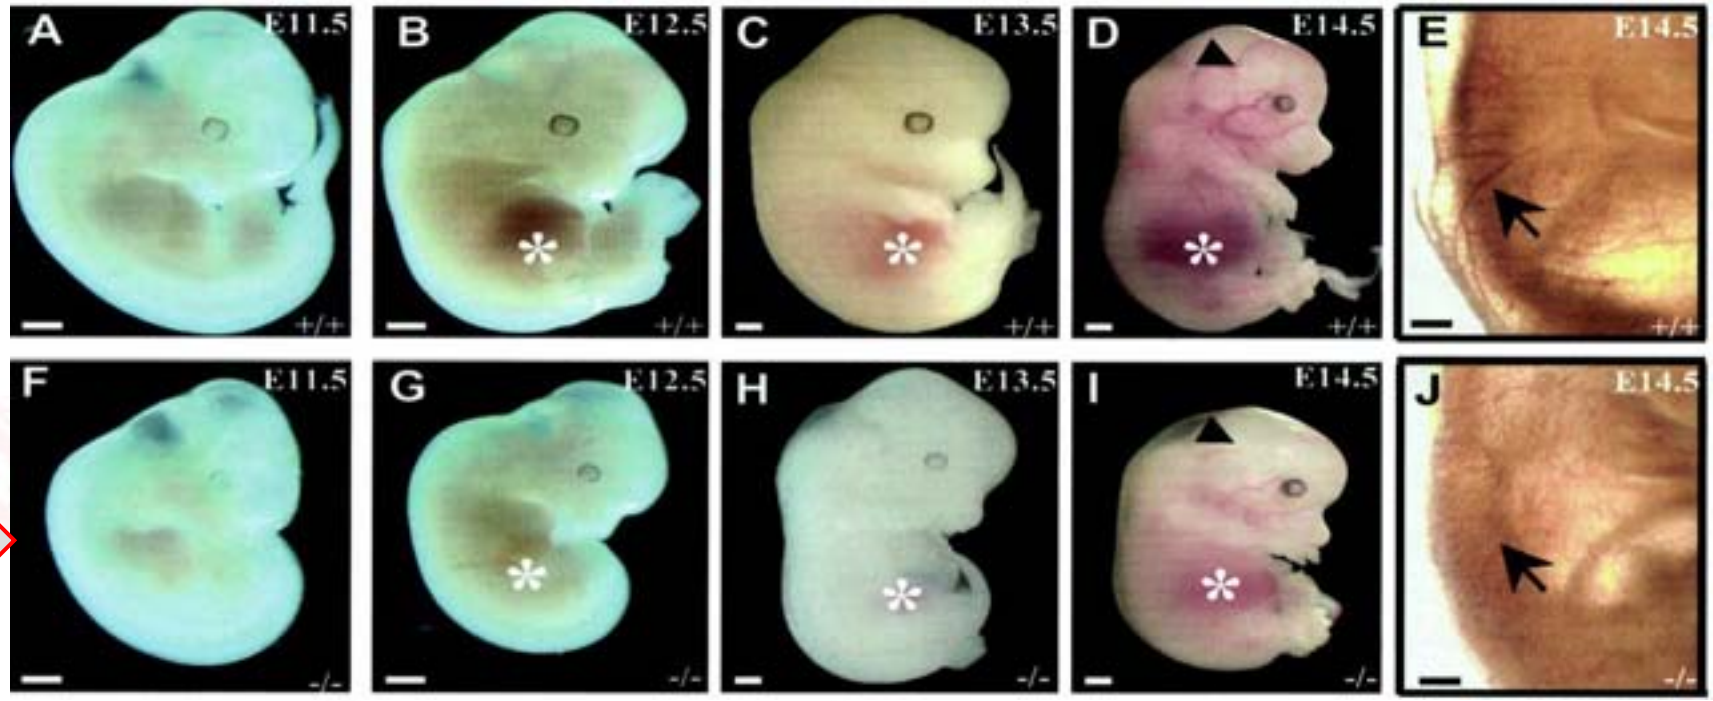


Thomas Thum
Break-out session
Tuesday 2PM

Dicer

First evidence for a regulatory role of miRs in vascular development

Mice homozygous for a hypomorphic allele of *Dicer* showed impaired developmental angiogenesis and died at days 12.5 - 14.5 of gestation



Low Dicer

Dicer generates short interfering RNAs (including miRNAs) from longer double-stranded RNAs.

miRNA Summary and Perspective

- miRs modulate the post-ischemic neovascularization responses at multiple levels

- miR therapeutic can directly target ischemic tissues in vivo and be used for ex-vivo enhancement of the proangiogenic capacities of stem and progenitor cells

- Circulating miRs might be novel predictive and pognostic markers in ischemic patients

- There is a huge potential for miR translational research

Conclusions

- Myocardial and limb ischaemia are still unmet medical needs
- Novel options and revisited approaches hold therapeutic potential to treat limb and myocardial ischaemia
- This area of research can deliver disappointments as well as huge satisfaction
- Basic science and translational approaches must progress together to the ultimate clinical goal.
