The myth of the "vulnerable plaque": transitioning from a focus on individual lesions to atherosclerotic disease burden for coronary artery disease risk assessment.

Abstract

The cardiovascular science community has pursued the quest to identify vulnerable atherosclerotic plaque in patients for decades, hoping to prevent acute coronary events. However, despite major advancements in imaging technology that allow visualization of rupture-prone plaques, clinical studies have not demonstrated improved risk prediction compared with traditional approaches. Considering the complex relationship between plaque rupture and acute coronary event risk suggested by pathology studies and confirmed by clinical investigations, these results are not surprising. This review summarizes the evidence supporting a multifaceted hypothesis of the natural history of atherosclerotic plaque rupture. Managing patients at risk of acute coronary events mandates a greater focus on the atherosclerotic disease burden rather than on features of individual plaques.

Time-Dependent Changes in Atherosclerotic Plaque Composition in Patients Undergoing Carotid Surgery

Guus W. van Lammeren, MD, PhD*; Hester M. den Ruijter, PhD*; Joyce E.P. Vrijenhoek, MD; Sander W. van der Laan, MSc; Evelyn Velema, MSc; Jean-Paul P.M. de Vries, MD, PhD; Dominique P.V. de Kleijn, PhD; Aryan Vink, MD, PhD; Gert Jan de Borst, MD, PhD; Frans L. Moll, MD, PhD; Michiel L. Bots, MD, PhD; Gerard Pasterkamp, MD, PhD

Background—Time-dependent trends in the incidence of cardiovascular disease have been reported in high-income countries. Because atherosclerosis underlies the majority of cardiovascular diseases, we investigated temporal changes in the composition of atherosclerotic plaques removed from patients undergoing carotid endarterectomy.

Methods and Results—The Athero-Express study is an ongoing, longitudinal, vascular biobank study that includes the collection of atherosclerotic plaques of patients undergoing primary carotid endarterectomy in the province of Utrecht from 2002 to 2011. Histopathologic features of plaques of 1583 patients were analyzed in intervals of 2 years. The analysis included quantification of collagen, calcifications, lipid cores, plaque thrombosis, macrophages, smooth muscle cells, and microvessels. Large atheroma, plaque thrombosis, macrophages, and calcifications were less frequently observed over time, with adjusted odds ratios of 0.72 (95% confidence interval, 0.650-0.789), 0.62 (95% confidence interval, 0.569-0.679), 0.87 (95% confidence interval, 0.800-0.940), and 0.75 (95% confidence interval, 0.692-0.816) per 2-year increase in time, respectively. These changes in plaque characteristics were consistently observed in patient subgroups presenting with stroke, transient ischemic attack, ocular symptoms, and asymptomatic patients. Concomitantly, risk factor management and secondary prevention strategies among vascular patients scheduled for carotid endarterectomy significantly improved over the past decade.

Conclusions—In conclusion, over the past decade, atherosclerotic plaques harvested during carotid endarterectomy show a time-dependent change in plaque composition characterized by a decrease in features currently believed to be causal for plaque instability. This appears to go hand in hand with improvements in risk factor management. (***Circulation*.2014;129:2269-2276.**)

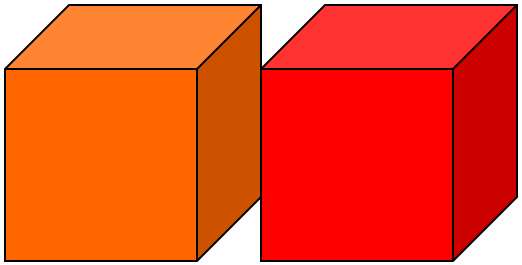
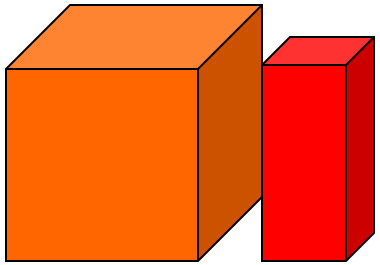
If underlying pathology is shifting: implications

University Medical Center Utrecht



Stable lesion

Vulnerable lesion



- In the presence of (a)symptomatic disease: much more stable lesions are observed.
- For increasing number of patients: Are we still chasing the right target, e.g. the “vulnerable plaque”?
- What does this imply for tissue and plasma biobanks (biomarkers): Do data and samples obtained before 2000 still represent current patient population?

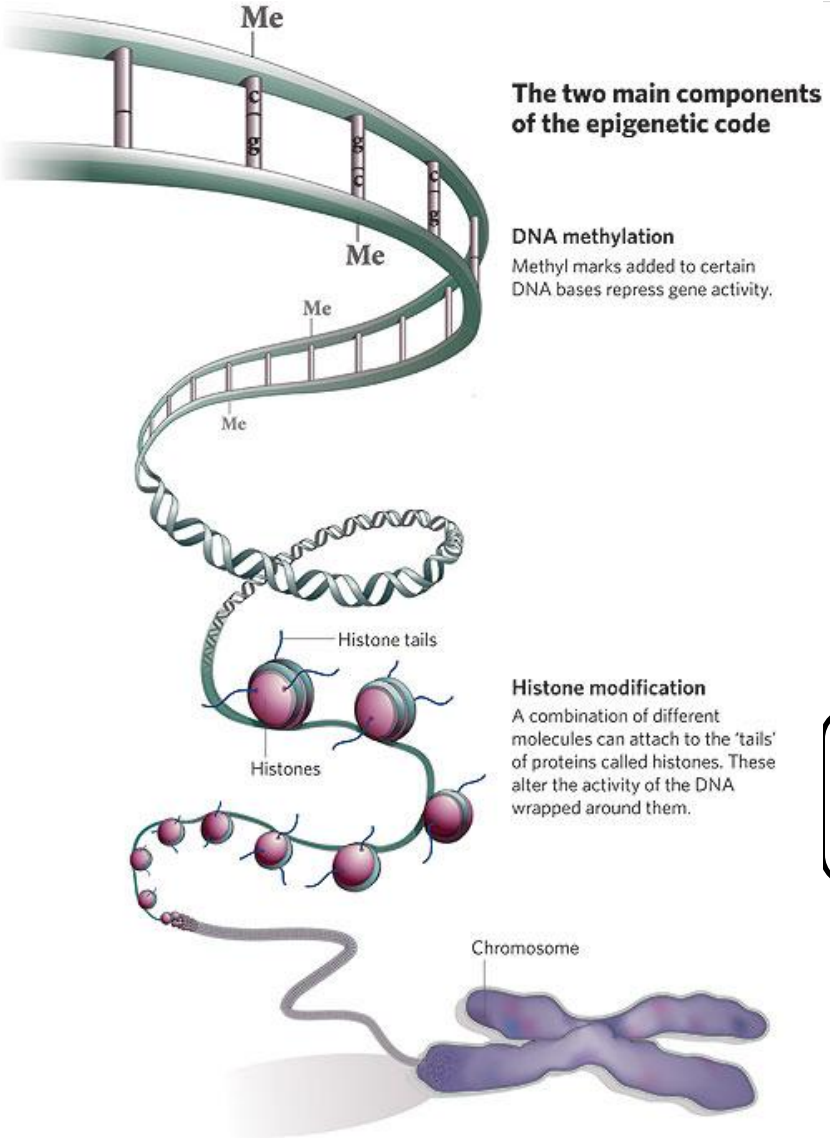
Epigenetic gene transcription regulation

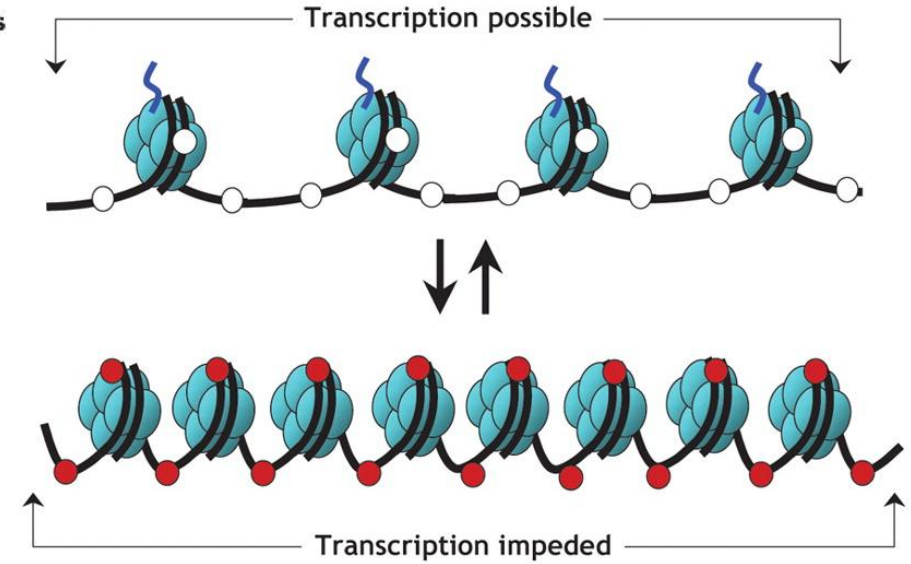
University Medical Center Utrecht



The two main components of the epigenetic code

DNA methylation
Methyl marks added to certain DNA bases repress gene activity.

Histone modification
A combination of different molecules can attach to the 'tails' of proteins called histones. These alter the activity of the DNA wrapped around them.



- DNA-methylation only occurs at Cytosine-Guanine (CpG)

- DNA-methylation is cell type specific

Next step: did methylation of DNA in plaques change in non smokers after banning smokers in public areas?
