What is CVD prevention?
A coordinated set of actions, at population and individual level, aimed at eradicating, eliminating or minimizing the impact of cardiovascular diseases and their related disability.

Why is CVD prevention relevant in general practice?
Atherosclerotic cardiovascular disease remains the leading cause of premature death worldwide. CVD affects both men and women; of all deaths before the age of 75 years in Europe, 42% are due to CVD in women and 38% in men. Most patients are followed up in primary care and screening the population for CVD risk factors is preferably done there.

Treatment of risk factors

**Smoking**: all smoking including exposure to passive smoking has to be avoided. Smoker to quit and offered assistance, if needed with pharmacotherapy.

**Nutrition**: advise on a healthy diet (ex. fruits and vegetables 500 gr daily), being the cornerstone of CVD prevention.

**Physical activity**: healthy adults of all ages should spend 2.5-5 hours a week on physical activity of at least moderate intensity (optimally 30 minutes or more daily, but any physical activity is better than none).

**Diabetes**:
- Target HbA1c for the prevention of CVD in diabetes: < 7.0% (<53 mmol/mol).
- Statins to all diabetic patients in order to reduce cardiovascular risk.

**Lipids**:
- In patients at very high CVD risk, the recommended LDL cholesterol target is <1.8 mmol/L (<70 mg/dL) or a
- ≥50% LDL-cholesterol reduction when the target level cannot be reached.

When do I assess CVD risk in the general practice population?

- The person asks for it.
- In men ≥40 years, and in women ≥50 years, or if postmenopausal.
- One or more risk factors are present: smoking, poor food habits or overweight, physical inactivity, hyperlipidaemia, hypertension or diabetes mellitus.
- There is a family history of premature CVD or of major risk factors such as hyperlipidaemia or diabetes.
- There are symptoms suggestive of CVD.

Three actions to be taken:
- History taking and clinical judgment.
- Assess CVD risk (use SCORE chart backside, unless the person has documented CVD, diabetes, chronic kidney disease or markedly raised single risk factors).
- Decide upon level of risk management.

Very high risk
- Documented CVD of any type.
- Diabetes with one or more risk factors or end organ damage.
- Severe chronic kidney disease.
- A calculated SCORE ≥10%.

High risk
- Markedly elevated single risk factors (dyslipidaemias, severe hypertension).
- Diabetes without risk factors or end organ damage.
- Moderate chronic kidney disease.
- A calculated SCORE of 1-5%.

Moderate risk
- A calculated SCORE of 5-10%.

Low risk
- SCORE <1% and free of any qualifiers that would put them at moderate risk.
