Radiation Exposure Bibliography

Concerns regarding radiation exposure and its effects during pregnancy are often a barrier preventing many women from pursuing a career in Interventional Cardiology. This article aims to provide a guide by describing the risk of radiation exposure to pregnant physicians and cardiac catheterisation personnel, to educate on appropriate radiation monitoring and to encourage mechanisms to reduce radiation exposure.

After an introduction on how to quantify the radiation exposure and defining its current magnitude in electrophysiology compared with the other sources of radiation, this paper offers some very practical advice on how to reduce exposure to patients and staff: how customization of the X-rays, workflow adaptation and shielding measures can be implemented in the cath lab.

The purpose of this survey was to evaluate physician’s and authorities policies and clinical practices when using occupational X-rays during ablation procedures and device implantation. It shows infrequent use of lead gloves, radiation absorbing pads and lead glass cabins, but increasing use of three-dimensional mapping systems to decrease X-ray radiation hazards.

The aim is to provide accurate and applicable data on occupational doses to the electrophysiology laboratory personnel. The study has shown that a procedure requiring 40 min of fluoroscopy yields a maximum effective dose of 129 microSv. A conservative estimate of the electrophysiologist's annual maximum permissible workload is 155 procedures. Radiation levels in the electrophysiology room are not negligible. Mitigation of occupational exposure is feasible through good fluoroscopy and working practices.

Point 9.2 of the consensus focus on radiation risks, dosimetry and methods to minimize exposure both for patients and staff.

This report addresses medical exposure of patients and the proper application of the fundamental principles. The emphasis is on the optimisation of radiological protection in diagnostic and interventional procedures and it was written with the intent of communicating directly with the relevant medical practitioners and supporting medical staff.

The Society of Cardiovascular Angiography and Interventions present a practical approach to assist cardiac catheterization laboratories in establishing a radiation safety program, including essential personnel, radiation monitoring, protective shielding, imaging equipment, and training/education. A procedure based review of radiation dose management is described including pre-procedure, procedure and post-procedure best practice recommendations. Specific radiation safety considerations are discussed including women and fluoroscopic procedures as well as patients with congenital and structural heart disease.

This science advisory from AHA addresses the fact that radiation dose to internal organs (fetus included) cannot be measured directly and that exposure needs to be estimated with generic modelling techniques used to calculate a broad indicator of risk that is not patient-specific. At the end, it gives recommendations on radiation reduction for the health care provider.

More recommendations from the ICRP to minimize radiation exposure.

This publication sets recommendation on education and training of medical staff (including medical students) and other healthcare professionals in the principles of radiation protection. It provides guidance regarding the necessary radiological protection education and training for use by: 1- health authorities, medical institutions, and professional bodies with responsibility for radiological protection in medicine; 2- the industry that produces and markets the equipment used in these procedures; and 3- universities and other academic institutions responsible for the education of professionals involved in the use of ionising radiation in health care. Advice is also provided on the accreditation and certification of the recommended education and training.
